THE AMERICAN SOCIETY OF
MECHANICAL ENGINEERS

VOLUME 37

JANUARY-DECEMBER 1915

THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS

29 West Thirty-ninth Street, New York

INDEX

THE JOURNAL OF THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS

Volume 37, January—December, 1915

PROCEEDINGS AND SOCIETY AFFAIRS

A

	PAGE
ABBOTT, ROBERT R. Comparison of the properties of a nickel carbon and manganese steel before and after heat treatment	440
Modern steels and their heat treatment	267
ADAMS, DAN. Relative value of private and purchased electric power for textile mills, Dec. vii	621
ADAMS, WALTER H. The Diesel engine and its applications in Southern California	621
ADLER, ALPHONSE. Modern electric elevator and elevator problems (D)	326
Air compressors, volume regulator for	170
ALDEN, GEORGE I. Operation of grinding wheels in machine grinding	16
The Washburn shops of the Worcester Polytechnic Institute	391
ALEXANDER, M. W., personal	733
ALLEN, WALTER C. Cleveland municipal electric light plant (D)	110
ALLEN, JEAN M., personal	663
ALLISON, JAMES E., personal	65
Amendment to C-50 of the constitution and by-laws	Jan. v
American Uniform Boiler Law Society	Dec. xix
ANDERSON, HAROLD BENTLEY, obituary	565
ANDREWS, JACOB ROBINSON, obituary	301
Annual meeting, 1914	1
1915	Oct. x, Nov. xvi, Dec. v
ANTHONY, J. T. Steam locomotives of to-day (D)	26
Application of engineering methods to the problems of the executive, director and trustee	Nov. xvi, 334
Applications for membership, Jan. vii, Feb. xiii, Meh. vii, Apl. xvii, May xiii, June xi, July xvi, Aug. ix, Sept. x, Oct. xv, Nov. xxv, Dec. xxi	384
ARMSTRONG, A. H. The electric locomotive	62, 195
Atlanta, meetings in	62, 195

B

	PAGE
AUEL, CARL BENNETT. Standardization in the factory	13
AVERILL, E. A. Steam locomotives of to-day (D)	33
Award, John Fritz Medal	36
BARCOCK, ALLEN H. A novel method of handling boilers to prevent corrosion and scale, Dec. vii	87
BAKER, CHARLES WHITING. Some factors in municipal engineering (D)	91
The engineer and publicity (D)	87
BAKER, NEWTON D. Some factors in municipal engineering (D)	86
BALL, WALTER SEEVER, obituary	731
BALLARD, FREDERICK W. The design and operation of the Cleveland municipal electric light plant	104
BALLENTINE, WILLIAM L., personal	663
BALLIN, ALFRED E., personal	663
BALLINGER, W. F. Reinforced concrete factory buildings (D)	10
BANGEL, PAUL A. Circulation in horizontal water tube boilers	Nov. xix
Performance and design of high vacuum surface condensers	Dec. viii
BARBA, W. P. Industrial safety and principles of management	692
BARSTOW, J. S. Turbines vs. engines in units of small capacities	Nov. xvii, 511
BARTH, CARL G. Effect of relative humidity on an oak tanned leather belt (D)	449
Relation between production and costs (D)	472
Basis for rational design of heat transfer apparatus	546
RAYLE, EMIL J., personal	615
RAYLEY, G. L. Engineering features of the Panama-Pacific International Exposition	571, 696, 699
BEACH, HAROLD K., personal	422
BECHTOLD, FRED J., personal	732
BEEDFORD, RUSSELL B., personal	133
BEHRND, B. A., personal	732
BEILCHER, THOMAS H., personal	301

	PAGE
BEMIS, EDWARD W. Cleveland municipal electric light plant (D)	110
BENNETT, THOMAS A., personal	245
BENNETT, W. A. Standardization of chilled iron crane wheels (D)	151
BERGER, JULIUS G., personal	65
BERGLOW, MYRON J., personal	422
BILLINGS, J. HARLAND, personal	733
BIRD, WILLIAM W. The effect of relative humidity on an oak tanned leather belt	May xii, 447
Relation between production and costs (D)	469
BIRKINSHIRE, JOHN, obituary	360
Boiler code, committee meeting	July vii
completion of	Mch. iii
discussion of	41
endorsed by the National Electric Light Association	Nov. xxiv
endorsement of	July xii
in effect in Ohio	June x
price of	April viii, June ix
progress on the report of committee	Feb. xi
second edition of	Nov. xxii
Boiler failures and what The American Society of Mechanical Engineers is doing to prevent them	509
inspection in Russia	Jan. vi
BOLGIANO, J. RALPH, personal	663
BOLTON, RICHARD P. Cleveland municipal electric light plant (D)	110
The future of the police arm from an engineering standpoint (D)	80
Modern electric elevator and elevator problems (D)	324
Some factors in municipal engineering (D)	85
Boston, meetings in	62, 64, 129, 195, 243, 506, 358
symposium on employment and education	277
BOWMAN, AUSTIN LORD, obituary	493
BOYD, JAMES E. Elasticity and strength of stoneware and porcelain	Nov. xx
BOYLE, CHARLES E. JR., personal	301
BRADSHAW, G. D. Address at Buffalo meeting	July iv
personal	616

NOTE: A discussor is distinguished from the author of a paper by (D) placed after the name of the paper.

30394

PUBLISHED MONTHLY BY

THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS

29 West Thirty-ninth Street, New York

PRICE 35 CENTS A COPY, \$3.00 A YEAR; TO MEMBERS AND AFFILIATES, 25 CENTS A COPY, \$2.00 A YEAR. POSTAGE TO CANADA, 50 CENTS ADDITIONAL; TO FOREIGN COUNTRIES \$1.00 ADDITIONAL

C 55. The Society as a body is not responsible for the statements of facts or opinions advanced in papers or discussions.

Entered as second-class matter, January 4, 1912, at the Postoffice, New York, N. Y., under the act of March 3, 1879

COMING MEETINGS OF THE SOCIETY

January 6, Boston, Mass., Engineers Club. Topic: Aviation, with addresses by G. S. Curtis, A. A. Merrill, and others.

January 7, Buffalo, N. Y. Subject: Recent Development in Steam Turbine Engineering, Prof. J. A. Moyer of Pennsylvania State College.

January 8, Chicago, Ill. Railroad meeting, with papers on Locomotive Superheaters and Stokers.

January 14, Philadelphia, Pa. Joint meeting with the Franklin Institute. Paper: Modern Steels and their Heat Treatment, by Robert R. Abbott.

January 28, Buffalo, N. Y. Subject: Manufacture of Portland Cement, by Prof. R. C. Carpenter of Cornell University.

January, New York City. Subject and date to be announced.

THE JOURNAL OF THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS

Volume 37

January 1915

Number 1

JOHN A. BRASHEAR

President of the Society for 1915

John A. Brashear was born in Brownsville, Pa., November 24, 1840. His father was a saddler, his mother the daughter of Nathaniel Smith, from whom young Brashear inherited his taste for science and mechanics, the grandfather having constructed one of the first telegraphic instruments made in Western Pennsylvania, and also succeeded in taking some of the earliest daguerreotypes.

The grandfather had a great love for astronomy and taught the constellations to his grandson when he was only eight years of age. About this time he had an opportunity to see the moon and Saturn through a small telescope made by a watchmaker of McKeesport, Pa., which had been brought to Brownsville, a small charge being made for the view. This left an indelible impression on the mind of young Brashear, and even at this early age he had a desire to own a telescope some day, perhaps, in the far distant future.

His education was confined to the common schools of Brownsville, but he found in his last two teachers men of large brains and a love for their calling, which made the little red brick school-house to him a real college and his only alma mater.

At 17 he was apprenticed to the patternmaking and engine-building trade at the works of John Snowden & Sons, and after finishing his trade, went to Louisville, Ky., where he engaged in engine-building with the firm of Dennis Long & Company.

While he was in Louisville the Civil War broke out and he came to Pittsburgh, where he took charge of the machinery of the Zug & Painter mill in 1862. In 1867 he was asked to take charge of the machinery in McKnight, Duncan & Company's mill, which he entirely rebuilt after a destructive fire. During his stay at this mill, Dr. George Barker of the University of Pennsylvania came to Pittsburgh to give a course of lectures on the spectrum analysis, a science then in its childhood, which Mr. Brashear heard, and as a result of which became so deeply interested in the subject that it was not long until he constructed a bisulphide of carbon prism and began the study himself.

After seven years with McKnight, Duncan & Com-

pany, his old friend Christopher Zug asked him to come to his mill again. The offer was accepted and he remained with the firm of Zug & Company until 1881, when he yielded to his great desire to construct astronomical instruments for amateurs, particularly in the line of silvered glass reflecting telescopes, which had not yet been made in this country except by Dr. Henry Draper, and decided to leave the rolling mill for good.

In 1862 Brashear married Phoebe Stewart, who was his faithful and devoted helpmate in all his early and later work, and the husband and wife spent three years making their first lens and constructing a 5-in. refractor. When this did not prove very satisfactory, they undertook a 12-in. reflecting telescope, the glass of which was broken by accident after two years of night labor, for all this work was done during Mr. Brashear's stay in the rolling mill.

Nothing daunted, the good wife had everything made ready in the little workshop the day after the accident, and in two months a new 12-in. telescope was ready for observation, and was used for many years in a study of celestial phenomena, including the question of changes on the moon's surface, comets and nebulae, for which the 12-in. telescope was particularly well suited.

Professor Langley early became interested in Mr. Brashear's work and entrusted him with a number of important pieces of apparatus, among them his accurate mirrors, solar storage energy apparatus, etc. At the time Professor Langley was making his study of the selective absorption of the earth's atmosphere and its relation to organic life upon the earth, he required accurate rock salt lenses and prisms, which had not been made with the precision demanded until the problem was solved by Mr. Brashear. The method was given to the scientific world in a paper read before the American Association of Science about 1885. Langley's memorable researches in this great field made him famous, and he never failed to give Mr. Brashear a fair share of the credit of making his discoveries possible.

Mr. William Thaw, the Pittsburgh philanthropist and a friend of Langley's, sent for Brashear, and insisted upon building him a better workshop, finally in-

ducing him to move to Allegheny, so as to be near the observatory. Here began a lasting friendship with Mr. Thaw and Professor Langley. For three years all the early experimental equipment for Langley's researches in aviation, aerodynamics and aerodromics was made in the Brashear laboratory.

Orders began to come in to the new workshop, especially in the line of spectroscopes, and about this time Professor Rowland of Johns Hopkins University, entrusted Mr. Brashear with the making of the delicate plates on which he was to rule his wonderful diffraction gratings.

About this time Mr. Brashear's daughter married Mr. McDowell, who at once joined in the work, soon proving himself to be a master in the production of accurate optical surfaces. Brashear has always given the largest share of credit to Mr. McDowell, his associate, who has succeeded in reaching the highest demands of modern research, in optical lines.

Dr. Charles Hastings of Yale University early became associated with the firm, and with his mastery of mathematical optics, computed the curves of many object glasses of the highest type, doing away with all empiricism. The last large objective computed by him, and only recently finished by Mr. McDowell, is the 30-in. glass for the Allegheny Observatory, which is said to be the most perfect glass in the world today. The mountings of many of the larger telescopes were constructed by Messrs. Warner and Swasey, Past-Presidents of the Society.

Spectroscopes of every description for research have been made in Mr. Brashear's shop for institutions all over the world, for both astronomical and physical research, spectroheliographs, for studies of the sun; indeed, such has been the progress of astronomical spectroscopy since the Brashear works turned out the first spectroscope for Professor Keeler, for use with the great telescope of the Lick observatory, that it seems a new science, and remarkable discoveries in celestial physics are coming to us every day. Putting the matter grossly, the Keeler spectroscope was thought to be over heavy, as it weighed 45 lb. The Porter spectroscope, made for the Allegheny Observatory, weighs nearly nine tons, with its counterpoises, etc.

The development of the astronomical photographic camera has been carried along as one of the principal features of the Brashear works. The double camera of the 40 centimeter photographic telescope of the Heidelberg Observatory is one of the products of the firm and is the handiwork of Mr. McDowell, whose skill and judgment were equal to any optical task, but who was unwilling to pass any work of precision without the final criticism of Mr. Brashear.

The delicate plane parallel mirrors made for the study of the International Standard Meter in terms of light waves, were made by Mr. McDowell, and were used with the Interferometer devised by Dr. Michelson, for whom the surfaces were made. The Standard

Meter has now an absolute value in something that can never be destroyed. The limiting error of these delicate surfaces was less than $1/200,000$ in., such is the precision demanded in modern scientific research.

Mr. Brashear early became interested in educational work, beginning among his fellow workmen in the rolling mill. He has given over five hundred lectures to working men's organizations, indeed, to all classes of citizens interested in the beauties of science. He has personally known most of the eminent men in science of the last forty years, has served as acting chancellor of the University of Pittsburgh, as acting director of the Allegheny Observatory, and has been a member of the Board of Trustees of the Carnegie Institute since its beginning, and also of the Carnegie Technical Schools, the University of Pittsburgh, and is chairman of the Observatory Committee, as well as of several other institutions of an educational character.

Five years ago he was entrusted with a fund of \$250,000 by a friend of education, for the betterment of teaching and teachers in the public schools of Pittsburgh. Forming a commission to assist him in carrying out the donor's wishes, 605 teachers have been sent to summer schools from Maine to California for study, rest and recreation, and the results have been invaluable.

Mr. Brashear was also for many years interested in another project for helpfulness, the building and equipping of an astronomical observatory as a memorial to Mr. Thaw and his son, and to Professor Langley's lifelong friend, Professor Keeler. For this institution \$300,000 was raised, which is now one of the finest and best equipped observatories in the world. Through Mr. Brashear's efforts one department in the new observatory is free, and in the five years it has been open to the public no less than 14,500 people have made use of the telescope or listened to lectures on astronomy. Under the dome of one of the memorial telescopes, a mausoleum has been constructed by the friends of Mr. Brashear and Professor Keeler, in which lie the ashes of Professor Keeler and also those of Mrs. Brashear, who passed away in 1910. On the tablet covering the ashes of Mrs. Brashear are the words: "We have loved the stars too fondly to be fearful of the night."

Mr. Brashear was elected an Honorary Member of this Society in 1908. He is also an Honorary Member and Past-President of the Engineers Society of Western Pennsylvania and of the Royal Astronomical Society of Canada, an active member of the Royal Astronomical Society of Great Britain, the British Astronomical Society, the Société Astronomique de France, the Société Astronomique de Belgique, the American Philosophical Society, the American Astronomical Society, the American Association for the Advancement of Science, the Academy of Science and Art, and others.

He received the gold medal of the Franklin Insti-

tute in 1910; the degree of LL.D. from Washington and Jefferson, and Wooster Universities, the degree of D.Sc. from Princeton and the University of Pittsburgh, and that of Doctor of Engineering from Stevens Institute of Technology.

THE ENGINEERING FOUNDATION

A noteworthy incident in the history of the profession of engineering in the United States will be the inauguration of The Engineering Foundation on January 27, 1915, in the auditorium of the United Engineering Society in New York.

The Engineering Foundation is the name given to a fund to be administered for the advancement of the Arts and Sciences connected with Engineering and the benefit of Mankind, the basis of which is the initial gift of a considerable sum by a noted engineer for this purpose. The American Society of Civil Engineers, the American Institute of Mining Engineers, The American Society of Mechanical Engineers and the American Institute of Electrical Engineers are to be represented equally in the administrative Board of The Engineering Foundation by election by the Board of Trustees of the United Engineering Society, which had been made the custodian of the fund. All members and friends of the engineering profession are invited to these inaugural ceremonies.

SUGGESTIONS FOR AMENDMENT TO C-50 OF THE CONSTITUTION AND BY-LAWS

The following letter has been sent to the members of the Council:

December 18, 1914

TO THE MEMBERS OF THE COUNCIL

OF THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS
GENTLEMEN:

At meetings of the Council held November 13 and December 1, 1914, the following resolutions were passed:

Resolved: That it is the sense of the Council that the present method of nominating officers of the Society be amended, and request the Committee on Constitution and By-Laws to prepare such amendments to the Constitution and By-Laws as may be necessary in order to permit members to express their choice for nominees.

CONSTITUTION AND BY-LAWS

Voted: That members of the present Council be requested to file with the Secretary for reference to the Council and Committee on Constitution and By-Laws, suggestions concerning any needed changes in the Constitution and By-Laws.

Under this action of the Council will you kindly send to the Secretary of the Society to be transmitted to the Committee on Constitution and By-Laws any suggestions which you would like to have considered by the Committee.

You would greatly facilitate the work of the Committee if we could have your suggestions in the hands of the Committee before January 20.

Yours very truly,

CALVIN W. RICE, *Secretary.*

COUNCIL NOTES

DECEMBER 1

At a meeting of the Council on December 1 a committee was appointed by the President to report at the next meeting suggestions as to the Local Meetings of the Society. This Committee consisted of F. R. Hutton, Chairman, A. M. Greene, H. G. Stott and W. F. M. Goss.

The following appointments of Honorary Vice-Presidents were confirmed: Annual Meeting of the American Society of Refrigerating Engineers, Dr. Chas. E. Lucke; Pan-American Scientific Congress, committee to cooperate with the Department of State, General Wm. H. Bixby, Chas. T. Plunkett, and the Secretary.

The report of the Committee of the John Fitch Memorial was received and placed on file.

The matter of the bequest of Rear-Admiral Melville which provides for the Melville prize medal for original work was referred to the Finance Committee.

It was voted to authorize the President to cooperate with the American Institute of Mining Engineers and to make appointments on a joint committee on turbo-blowers.

DECEMBER 4

At a meeting of the Council on December 4, the new officers were formally introduced.

It was voted that, in accordance with resolutions adopted by the committee appointed to consider and report on Local Meetings of the Society, a Committee on Sections, consisting of five members, be appointed by the Council which shall confer with the various sections and promote their interests.

In this Society it has always been customary to elect as officers of the Society and to appoint as members of committees the most eminent men in the profession, with the definite understanding that the actual labor of the committee shall be performed by the Secretary and a competent staff.

This is in distinction from all other societies which have succeeded in getting sufficiently able and representative men who not only have served on the board and committees, but themselves have performed the work or had it done without expense to the society.

In order to insure that what is done may be performed as efficiently as possible, it was voted that a committee, to be known as the Committee on Administration, be appointed, to investigate and report upon the economical operation of the Society's administration.

It is to be hoped that as time goes on the members will feel that they owe it to their profession to give their services to such an extent that they shall personally undertake the duties of the various committees on which they are appointed and thus perform the work better than any one that can be employed, and in the discussions on the meetings of the Society the em-

phasis will be on the thing to be accomplished and not on its cost.

John R. Freeman was appointed a member of the Board of Trustees of the United Engineering Society, to succeed Fred J. Miller, whose term of office has expired and who, having served one term, was under the Constitution not eligible for re-election.

Dr. John A. Brashear was reappointed to succeed himself as representative on the John Fritz Medal Board of Award, to serve for a term of four years.

It was voted that the Publication Committee be requested to prepare a circular regarding the form of publication of The Journal and the continuance of the publication of the Transactions in its present form, to be submitted to the membership for letter ballot in accordance with the vote of the Annual Meeting.

The following Executive Committee of the Council was appointed for 1915: John A. Brashear, President, Chairman; H. L. Gantt, Vice-Chairman; A. M. Greene, Jr.; Henry Hess; Spencer Miller; H. G. Reist; and James R. Sague.

CALVIN W. RICE, *Secretary*.

BOILER INSPECTION IN RUSSIA

In connection with the work of the Committee on Boiler Specifications, a statement secured by the editor of the Foreign Review of boiler inspection in Russia is of interest. The main work of boiler inspection is concentrated in the hands of the Ministry of Manufactures which carries it on through its factory inspectors. As the main work of the factory inspection in that country is concerned with the supervision of the proper application of the rather complicated and strict labor laws, there has been a feeling for a long time that it would be best to select the inspectors from men who had had training in legal and economic questions, but the fact that the inspectors had to inspect the boiler equipment of factories limited their selection to graduates of engineering schools exclusively. As a result, a law has been recently worked out for referring the entire matter of boiler inspection to Boiler Inspection Associations, which are private organizations, but which operate under government supervision.

At the same time, there is a pronounced tendency to make the boiler inspection laws more uniform than they have been hitherto. While the laws generally extended to the entire country, there has been a certain lack of uniformity due to the fact that certain plants have been under the supervision of the Ministry of the Interior, and others, especially boiler plants on river and canal steamers, under that of the Ministry of Ways of Communication, these two ministries often promulgating regulations different from those of the Ministry of Manufactures, which governed the inspection in the majority of factories. The regulations published by the Ministry of Ways of Communication in 1913 for "the installation and testing of boiler and steam pip-

ing on vessels on internal waterways," are in closer agreement with the rules of factory boiler inspection than have been the case hitherto, and it is expected that, as soon as the war is over, a uniform boiler code will be adopted for the entire country.

GREETINGS FROM DR. BRASHEAR

It was a pleasure to receive at the Christmas season a telegram containing greetings from President Brashear, and through the medium of The Journal these are extended to the membership at large. The telegram reads as follows:

DEAR MR. RICE:

May I send through you my most kindly Christmas greetings to every member of the A.S.M.E. and all affiliated societies, wishing them health, happiness and prosperity, and may all have an ever present spirit of helpfulness in the great work, but pushing outward the borders of human knowledge.

Always cordially yours,
JOHN ALFRED BRASHEAR,
Member of the Other Fellows Club

A STUDENT BRANCH CONFERENCE

During the Annual Meeting of the Society in December a conference was held on the subject of the Student Branches of the Society. Prof. F. R. Hutton, Chairman of the Committee, presided. The interchange of experience and discussion of the differing problems of each institution was thought of such value that it was decided that a similar conference should be made part of the program of every Annual Meeting:

The topics broached covered:

- (1) The advisability of having the Society office notify each member of a branch of his election to such membership
- (2) The advantage of a diploma or certificate of membership; or of a button or lapel-badge
- (3) The difficulties when Seniors only were members of a student branch in a transmittal of an *esprit de corps* to the succeeding class
- (4) The possibilities of using The Journal of the Society in seminar work of teaching
- (5) The advantage of beginning an academic (and a branch) year by a social meeting at which also some outside engineer should speak and refreshments be a feature
- (6) The advantages of stimulating participation of the student himself by paper and by discussion, even if the plan of getting talent from outside had to be curtailed to accomplish this result. Case School accepts papers presented before the branch as equivalent to required work for the degree, when of satisfactory quality
- (7) The ideal (of Brooklyn Polytechnic Branch) of making the branch tell both for the engineering education of the members and for their so-

cial intercourse and their becoming "experts in friendship"

- (8) The use of the stimulus of prizes for student papers before the branch (Hess Prizes) in promoting research work in laboratory or library and outside of the required curriculum for the degree
- (9) Query raised: Does the requirement of a \$2 subscription for the A.S.M.E. Journal keep any man from joining a Student Branch?
- (10) Can students in course be members of the branch organization without paying a \$2 Journal subscription?
- (11) Suggestion offered: That one address per year by an A.S.M.E. member of experience be a feature of branch life; that a booklet covering the advantages of membership in a Student Branch be prepared by the Society, and it be made the duty of the professor who is honorary president of the branch to see each spring that these get into the hands of the class becoming eligible to membership; that lower classmen be always invited to branch meetings, while right to office and to vote be prerogatives of the upper classmen.
- (12) One institution has a society of students for each year, the topics being chosen and pursued with some regard to the advancement in the course of study. The senior society becomes the A.S.M.E. branch by promotion, and hence a pride is felt in the branch, because it has been looked forward to
- (13) That the A.S.M.E. invite the Student Branches to send delegates as such to the Annual (or semi-annual) Meeting of the Society, such accredited delegates to have the rights of members in attendance
- (14) That a reunion of such delegates and of the honorary chairman of the branches be a stated feature of Society conventions
- (15) That a report and summary of the meeting be published in The Journal for the information of Student Branches and their officers.
- (16) That the Student Branches are potentialities of great mutual service, to the men and to the Society

F. R. H.

JOURNAL ANNOUNCEMENT

During the past year The Journal has been made to include the Transactions of the Society, comprising papers and discussion given at the Annual and Spring Meetings and many of the papers given at local meetings of the Society. The Annual and Spring Meeting papers have been published in full, except in cases where they have been previously printed in earlier numbers of The Journal.

In the provision which has been made for binding, it was decided to include in the bound volume the papers and discussion mentioned above, and in addition the Review Section which contains abstracts of articles published in the foreign press and the proceedings of engineering societies. As announced elsewhere, covers for binding will be supplied for 75 cents. Any member ordering a cover may have the item charged to his account.

As announced in the December Journal, however, the Council has voted to continue the annual volume of Transactions in its original form in library binding for at least another year, so that members will receive in this volume as heretofore the papers and discussion given at the Annual and Spring Meetings, which will duplicate the reports of these meetings as published in The Journal. The additional matter in The Journal, which will not be contained in Transactions, consists of the monthly meeting papers and the abstracts of articles in the Review Section.

For the coming year, in view of the decision to publish Transactions as a separate volume, the papers and discussion will be printed in The Journal in abstract, as has been done in the present issue. The object will be to present to the membership in a brief and comprehensive form reports of meetings as soon as possible after they have taken place, so that it will not be necessary to wait until the end of the year before receiving this information.

All members are asked to give particular attention to this method of handling the publications of the Society, as in accordance with the resolution adopted at the Annual Meeting they will be asked to express their preference in the near future.

APPLICATIONS FOR MEMBERSHIP

Members are requested to scrutinize with the utmost care the following list of candidates who have filed applications for membership in the Society. These are subdivided according to the grades for which their age would qualify them and not with regard to professional qualifications, i. e., the age of those under the first heading would place them under either Member, Associate or Associate-Member, those in the next class under Associate-Member or Junior, while those in the third class are qualified for Junior grade only. The Membership Committee, and in turn the Council, urge the members to assume their share of the responsibility of receiving these candidates into the Membership by advising the Secretary promptly of anyone whose eligibility for membership is in any way questioned. All correspondence in regard to such matters is strictly confidential and is solely for the good of the Society, which it is the duty of every member to promote. These candidates will be balloted upon by the Council unless objection is received before February 10, 1915.

NEW APPLICATIONS

FOR CONSIDERATION AS MEMBER, ASSOCIATE OR ASSOCIATE-MEMBER

ALRICH, HERBERT W., Asst. Engr. of Constr., Consolidated Gas Co., New York

BARDEN, JULIUS C., Assoc. Dir., Bureau of Inspection and Accident Prevention, Aetna Life Ins. Co., Hartford, Conn.

BARRETT, WILLIAM F., Cons. Engr., Chicago, Ill., and New York

BEAN, CLARENCE H., Asst. Supt. Motor Pwr., Armour & Co., Chicago, Ill.

BLAKE, FREDERICK W., Genl. Mgr., United Railways of Yucatan, Yucatan, Mex.

DADLEY, JAMES W., Efficiency Engr., The Celluloid Co., Newark, N. J.

DIERMAN, WILLIAM, Pur. Agt., Society of Electrical Lighting, Paris, France

DUFF, HOWARD, First Asst. Chief, Testing Bureau, Brooklyn Rapid Transit Co., Brooklyn, N. Y.

FERGUSON, SMITH F., Cons. Engr., Nicholas S. Hill Jr., and S. F. Ferguson, New York

FORD, HENRY, Pres., Ford Motor Co., Detroit, Mich.

FRANCIS, IRA J., With John A. Roebling's Sons Co., Los Angeles, Cal.

GILMORE, THOMAS N., Ch. Engr., Westinghouse Church Kerr & Co., New York

HAMILTON, HENRY A., Asst. Mgr., Muegel Box Co., Jersey City, N. J.

HARDY, CLEMENT A., With Whiting Foundry Equipment Co., Harvey, Ill.

HOSFORD, WILLIAM F., Engr. of Methods, Western Elec. Co., Chicago, Ill.

KELLOGG, RAYMOND M., Asst. Engr., Gas Dept., Westchester, Ltg. Co., Mt. Vernon, N. Y.

THE ANNUAL MEETING

HELD AT THE SOCIETY HEADQUARTERS, NEW YORK, DECEMBER 1—4

THIS meeting, which was one of the most successful in the history of the Society, was notable for the unusual number of papers devoted to many branches of engineering. Interesting papers were contributed on subjects in Industrial Engineering, Textiles, Machine Shop Practice, Railroad Engineering, Public Service, Iron and Steel, Hoisting and Conveying, Cement Manufacture, etc., and unusual interest was shown in all the sessions, of which there was a total of fifteen. One of the most important features of the meeting was the discussion of the Progress Report of the Boiler Specifications Committee, which occupied six sessions. The attendance at this meeting was the largest in the history of the Society.

The thirty-fifth Annual Meeting of the Society, held December 1-4, 1914, in the Engineering Societies Building, New York, was notable for its unusually large number of professional papers and technical sessions, and for the discussion of the preliminary report of the Boiler Code Committee, the latter alone

Meetings of the Society in New York, were attractive and well attended. The usual presidential reception was held in the Society rooms on Tuesday evening with a large attendance, and on Wednesday afternoon the rooms were the scene of a successful reception and the dance given by the Ladies' Committee, Mrs. Ed-

MAIN AUDITORIUM OF THE ENGINEERING SOCIETIES BUILDING WHERE THE LARGER OF THE PROFESSIONAL SESSIONS ARE HELD

extending through six sessions. In all a total of 27 papers were read, besides the address of President Hartness on Tuesday evening, and 15 sessions were held, including those on the Boiler Code, there being sometimes three simultaneous sessions under way, and on Thursday afternoon four were in progress at the same time. The papers covered a wide range of subjects and were effective in drawing a large audience. The attendance at the meeting was the largest in the history of the Society, the total registration being 1367, of which 821 were members.

The social features of the meeting, under the supervision of the House Committee and the Committee on

ward Van Winkle, Chairman. The chief social event came on Thursday evening at the Hotel Astor, where the annual reunion took the form of a dinner dance. More than 300 covers were laid in the grand ball room, the guests progressing from table to table for the various courses. There was dancing between courses as well as at the conclusion of the dinner. This dinner dance was an innovation which apparently was very pleasant to every one and many expressed the hope that it might be made a permanent feature of the Annual Meetings. Unlike the usual dinner or formal reception, it gave every person present an opportunity to meet a large number of others and the event pro-

moted sociability to the greatest possible degree. Another delightful occasion was the luncheon tendered to the ladies of the Society on Thursday in the Orangerie of the Hotel Astor by Mrs. Harrington Emerson, which was attended by about 125.

The presentation of the John Fritz Medal on Wednesday evening, together with the interesting addresses given by Dr. James Douglas, Honorary Member and Past-President of the American Institute of Mining Engineers, and Dr. S. W. Stratton, director of the Bureau of Standards at Washington, proved to be another interesting feature. A more complete account is given elsewhere in *The Journal*.

In connection with the meeting, the engineering alumni of nine colleges held reunions on Friday evening, following the practice of last year.

OPENING SESSION

On Tuesday evening, President James Hartness gave his address on the subject, *The Human Element the Key to the Economic Problem*. This address presented an analysis of the human characteristics that influence a man in his various efforts, and especially his accomplishments in industrial work, and showed the bearing which these same characteristics have on the industries themselves. He contended that large organizations are essential and that rightly conducted they are beneficial, since they seem to provide more nearly the conditions required for the happiness and success of the workman, when we come to analyze what the workman actually needs to inspire his best efforts.

Preceding the address there was a report given by the tellers of election of officers, showing the following votes cast: For President, John A. Brashear, 2034; for Vice-Presidents, Henry Hess, 2031; Geo. W. Dickie, 2033; James E. Sague, 2034; for Managers, Charles T. Main, 2035; Spencer Miller, 2036; Max Toltz, 2032; and, to fill the unexpired term of the late Alfred Noble, Morris L. Cooke, 1171, George J. Foran, 859; for Treasurer, Wm. H. Wiley, 2034.

An abstract of President Hartness' address follows, and the complete report will be published in the next volume of the *Transactions*.

ABSTRACT OF THE PRESIDENT'S ADDRESS

The world of mechanism has become so intricate and complex that it has gone beyond the capacity of any single individual. Each one must be content to comprehend only a small part, and only by selecting the character and limiting the amount of material that is taken into our individual minds can we hope to accomplish the best results. Under ordinary conditions the mind receives impressions from all directions, which, if unguided, may result in an undesirable trend in our personality and ability. On the other hand, by concentrating on those things which are of the greatest use to us, keeping in mind the laws of psychology, we may make a better use of our mental energy. The engi-

neer should devote a part of his time to the care and study of his thinking machine instead of devoting it all to the machine created by that thinking machine. We should not overload our minds with data to the exclusion of thoughts of an initiative character.

Man is a creature of habit to an extent that renders this characteristic a dominant one, and the most efficient use of mind and body demands a scheme of life that permits each one to take advantage of this fact.

Specialization and repetition, by which habit is formed, are both essential to success. Carrying the principles of the individual into the realm of organized industry, it is a fact that large organizations are essential as affording an opportunity for the most complete sub-division of work and the greatest degree of specialization, both of which lead to the most effective employment of human energy. A most important element of the large manufacturing plant is its organization. Without this, the buildings and equipment are of little value. Antagonism to the large organizations should be directed against corrupt practices, and not against the organization itself, which involves the workers' interest. The greatest good to the greatest number requires that we take into consideration each human being, his desires and his needs in finding the work for which he is best endowed.

Granting that the large organization is essential in this age, not only in bringing out the best in the individual but in maintaining the supremacy of American industry against foreign competition, may it not be that we may approach the ideal which we may assume to be somewhat as follows for a large industrial plant:

It should have a capital equal to or as large as any competing organization. If possible it should have a small harmonious board of directors with an able leader. But if the directors merely represent the monied interests without special knowledge of the industry, then it would be sufficient if they were capable of appointing an able staff of officers, the chief executive of which should combine a knowledge of the technical and business side of the industry with the fullest possible conception of the human element. He should stand firmly for the cardinal principles of industrial economies as based on the human characteristics. Each officer should possess some special knowledge essential to the organization, so that the combined staff would have a general knowledge of all the various branches.

The chief executive should make it known that long continuity in service of each man in office will be given the first place in the scheme of management, and this should not only include the officers, but it should be the key to the management of the entire organization.

The period of years of service of each man in the organization in a given task or in a given office should compare favorably with competing organization.

It should be the aim of the executives to fill each position throughout the entire organization with someone who considers that position the best place in the world for him. Each officer and each workman should have a live interest in his part of the work. Each one should by specialization become the most efficient in his particular work. The interest of the officer or worker should be maintained by some fitting stimulus, and each one should be protected so far as possible from influences calculated to induce discontent.

Each man should be treated in a respectful manner. Needless direction or heartless correction by an overbearing executive should not be permitted. Criticism or reprimand should not be uttered in the presence of others, for the best control of the organization comes from contact with the better side of man, and that side is not reached by one who rides rough-shod over a man's self-respect.

Personal dignity and self-respect is an important characteristic in everyone. It is not the exclusive quality of those whose self-respect is very apparent, nor is it limited to those whose natural conduct and bearing indicate their high regard of the esteem of others. It is to be found in the entire human family, and he who fails to see it, even in an apparently careless person, is blind to a very important part of the human spectrum.

As these truths become known will it not be possible to formulate general rules of management of industrial organizations that will be of great value to both the investor and the promoter? With such rules the investor could see to what extent an organization conforms to success standards. There would be in addition to the regular treasurer's report a human report. The human report would begin with a description of the directors and go through the entire organization. This report would contain a statement regarding the elements of harmony of organization; of length of service of manager and workers; the frequency of change of methods or article manufactured; intelligence of executives in the management of men; the degree of contentment of each member; the extent to which each man in the organization approaches the best position for which he is endowed and how nearly he obtains the best remuneration for which he is qualified; the extent to which the management recognizes the inertia of habit of both mind and body; the degree in which the various men in the organization approximate the condition of highest efficiency; the extent to which the management goes in expression of appreciation; the degree of its knowledge of the most important characteristics of man as indicated by his inner motives and desires and the condition of his mind as he goes to his home at night. No mention is made here of the conditions of buildings from the point of sanitation and comfort, for such conditions are now closely scanned; but mention has been made of a few of those other con-

ditions that must some day be measured just as we now measure power and other less vital things.

All of these elements should be carefully appraised and the average should be the rating of the company. The investor who considers this human rating with the treasurer's statement will seldom make a mistake in estimating the true worth of an industrial organization.

May we not hope that tabulations of these various elements taken from a variety of industries will lead to establishing a standard that will be a guide to both the manager and the investor?

Surely the investor should look with distrust upon a management that is always changing officers, changing men, changing models, changing methods without regard to the inertia of habit and the human element which is the life blood of every organization. He would also look with doubt on any scheme of management that allows the careless employment and discharge of men without due regard to the loss involved by such changes, for the perpetual changing of men is equivalent to the change of character of work in its handicap to industrial efficiency.

WEDNESDAY MORNING SESSION

The annual business meeting occupied the session of Wednesday morning, and the annual reports of the Council and Standing Committees were presented by the Secretary. The committee reports were printed in the December issue of *The Journal* and the Council report will appear in Volume 36 of *Transactions*.

In presenting the report of the Council the Secretary called attention to the varied work which the Society is successfully carrying on. Standardization work has been actively followed by the committees on flanges, pipe threads, boiler specifications; dimensions in screw threads; threads for fixtures and fittings; changes in the patent laws of the United States; specifications for fire hose and the tests for hose; power tests, a most voluminous report comprising standard methods for testing prime movers and all types of auxiliary apparatus; researches into the subject of standardization of safety valves; and standardization of commercial filters.

As a further development of the Society's work and a part of the work of the Committee on Meetings, subcommittees are at work in a great variety of branches of the engineering profession, such as the science of administration, cement, fire protection, air machinery, depreciation and obsolescence, hoisting and conveying, industrial building, iron and steel, machine shop practice, railroads, textiles, and a new committee on protection of industrial workers. Five of these committees have produced papers or reports for the Annual Meeting. It is the expectation that eventually all committees will not only make comprehensive reports on the progress of their branch of engineering, but fur-

nish one or more specific papers of major importance. It is thus intended that the Transactions shall contain each year an authoritative review of the state of the art.

Prof. F. R. Hutton presented a report of the Committee on Society History, describing what the history would aim to do, and stating that it had been found necessary to issue it by subscription. The manuscript has been prepared by the painstaking labor of Professor Hutton whose familiarity with every detail of the Society's activities from its organization has made it possible to introduce a great deal of matter of general interest beyond what is included in the formal

READING ROOM

THE VIEWS ON THIS PAGE SHOW THE THREE LARGE CONNECTING ROOMS AT THE HEADQUARTERS OF THE SOCIETY WHICH WHEN THROWN TOGETHER PROVIDE A SPACIOUS AND ATTRACTIVE GATHERING PLACE FOR MANY OF THE SOCIAL EVENTS OF THE ANNUAL MEETING. HERE THE PRESIDENT'S RECEPTION AND THE LADIES' RECEPTION WERE HELD

I. E. Moulthrop then reported for the Committee on Increase of Membership and outlined its work. During the fiscal year 1913-1914, 1195 applications have been received, making a gain of over 14 per cent more than were received during the previous year. During the four years since the establishment of the committee, 3418 applications have been received, a number almost equal to the total membership, 3899, of the Society previous to that time.

Mr. Moulthrop laid stress on the importance of welcoming the large number of new members who are coming into the Society. At every convention there are

SECRETARY'S OFFICE

COUNCIL ROOM

records of the volumes of the Transactions. The text is enlivened by an account of many incidents relating especially to the early meetings of the Society by which the personal characteristics of the small group constituting the membership are vividly portrayed. Of perhaps still greater interest is the historical development of policies and precedents in the Society which have grown up with the years and which are somewhat apart from matters of definite history in the usual sense.

new faces and it is difficult to remember names where members have been met only once or twice before, and he knew that every effort would be made to introduce such members and to give them a hearty welcome to the convention. To this end the plan had been adopted of giving to each new member a blue ribbon to wear in his lapel and all the older members had been requested to greet and introduce these new members.

The amendment to C-45 of the Constitution relating to the addition of a standing committee on Standard-

ization was then read by the chairman of the Committee on Constitution and By-Laws, Jesse M. Smith, and ordered by the meeting submitted for letter ballot.

The following resolution was then adopted:

Resolved: That the form of publication of The Journal and the continuance of the publication of the Transactions in its present form be made the subjects of a referendum mail vote to the membership of this Society and that the form of letter ballot be decided upon by the Council.

The remainder of the meeting was devoted to a discussion of the Boiler Code, reported elsewhere in this issue.

PROFESSIONAL SESSIONS

The professional sessions will be reported in detail in this and succeeding issues of The Journal, with a more complete printing of the papers and discussion in the annual volume of the Transactions. As in recent years, the Committee on Meetings has aimed to have sub-committees in charge of sessions or at least to submit papers in their respective fields, and this year there were papers offered by five committees, and an all-day session on Thursday on the Relation of the Engineer to Public Service in Municipalities, in charge of the Public Relations Committee of the Society, was made the feature of the convention. This meeting was opened by the Hon. John Purroy Mitchel, Mayor of the City of New York, and many prominent members of the Society were on the platform, among them Andrew Carnegie who at the close of Mayor Mitchel's address made a few humorous remarks, to which President-Elect Brashers, an intimate friend of Mr. Carnegie, retaliated in kind.

The sessions were well attended and the capacity which the Society has developed for conducting professional meetings was well illustrated on Thursday afternoon when there were two largely attended sessions in progress simultaneously, besides a session on the subject of Cement Manufacture with 40 or 50 present, and a meeting for the discussion of the Boiler Code with an attendance of 100.

The following is a list of the papers presented during the convention:

FLOOR SURFACES IN FIREPROOF BUILDINGS, Sanford E. Thompson.

REINFORCED-CONCRETE FACTORY BUILDINGS, F. W. Deah.

MEASURING EFFICIENCY, H. L. Gantt.

STANDARDIZATION IN THE FACTORY, C. B. Auld.

OPERATION OF GRINDING WHEELS IN MACHINE GRINDING, Geo. I. Alden.

FRICTION LOSSES IN THE UNIVERSAL JOINT, P. F. Walker and W. J. Malcolmson.

STEAM LOCOMOTIVES OF TODAY: Report of the Sub-Committee on Railroads.

THE FUTURE OF THE POLICE ARM FROM AN ENGINEERING STANDPOINT, Henry Bräuer.

SOME FACTORS IN MUNICIPAL ENGINEERING, Morris L. Cooke.

THE NEW CHARTER FOR ST. LOUIS, Edward Flad.

THE ENGINEER AND PUBLICITY, C. E. Drayer.

SNOW REMOVAL: A Report of the Committee on Resolu-

tions of the Snow Removal Conference held in Philadelphia, April 16 and 17, 1914.

THE DESIGN AND OPERATION OF THE CLEVELAND MUNICIPAL ELECTRIC LIGHT PLANT, Frederick W. Ballard.

THE HANDLING OF SEWAGE SLUDGE, George S. Webster.

TRAINING FOR THE MUNICIPAL SERVICE IN GERMANY, Clyde Lyndon King.

A STUDY OF CLEANING FILTER SANDS WITH NO OPPORTUNITY FOR BONUS PAYMENTS, Sanford E. Thompson.

FACTORS IN HARDENING TOOL STEEL, John A. Mathews and Howard J. Stagg, Jr.

STANDARDIZATION OF CHILLED IRON CRANE WHEELS, F. K. Vial.

THE MECHANICAL ELIMINATION OF SEAMS IN STEEL PRODUCTS, NOTABLY STEEL RAILS, R. W. Hurt.

TOPICAL DISCUSSION ON ALLOY STEELS.

A RATE-FLOW METER, H. C. Hayes.

LABORATORY FOR TESTING AND INVESTIGATING LIQUID FLOW METERS OF LARGE CAPACITY, W. S. Giele.

A NEW VOLUME REGULATOR FOR AIR COMPRESSORS, Ragnar Wikander.

PHYSICAL LAWS OF METHANE GAS, P. F. Walker.

THE CLINKERING OF COAL, Lionel S. Marks.

DAMAGES FOR LOSS OF WATER POWER, F. W. Dear.

EXCURSIONS

A number of interesting and instructive excursions were arranged by the committee in charge, John P. Neff, Chairman, and proved unusually successful.

A party of 20 made the trip to Ellis Island on Wednesday morning, under the guidance of H. R. Cobleigh, and were shown through all the departments of the immigrant station. The visitors were particularly interested in the tests which are applied to the immigrants to determine the desirability of admitting them, and also in the restaurant where the immigrants are fed at a cost of 24 cents a day. Leaflets placed in the hands of each visitor gave briefly the salient features of the building and the methods pursued in the work.

The Hill Building was visited by a party of 25 on Wednesday afternoon, C. W. Dibble acting as guide. This is the heaviest and most substantial building of its size in New York, not a single piece of wood entering into its construction. It is essentially a printer's building, and although only 12 stories in height is as tall as an ordinary 17-story building. The building is sealed, all air being filtered and washed before being forced to the different floors. The three intake fans handle 47,000 cu. ft. of air per minute, while the two exhaust fans on the roof handle 67,000 cu. ft. per minute. Drinking water is filtered, cooled in an ice plant, and supplied to bubblers on each floor. A pressure sprinkler system is used throughout, and in addition there are two automatic fire alarms on each floor connecting directly with a firehouse less than a block away. The office floor of the Hill Company is completely covered with interlocking rubber tiling, which almost eliminates all noise of walking, and in addition to this Noiseless typewriters are used. Machine dictation is used exclusively. All the furniture except the chairs is of steel, and the lighting is entirely indirect. The building has its own power plant, containing three 250-kw. Erie City engines of the Lentz type. The

boiler plant is of Heine boilers, equipped with Taylor stokers, and so arranged that there is no necessity for shoveling coal. This is delivered to the stokers by a bucket, working direct from the coal bunkers, and the ashes are removed by vacuum and carried up into an ash container where they are automatically sprinkled. They fall by gravity into ash carts driven under the ash storage. Buses provided by the company conveyed the party to and from the building.

A party of 38 visited the new long distance telephone office on Walker Street on Wednesday afternoon, conducted by Francis P. Davis. Upon arriving at the building the party was divided into groups of five, with three guides to each. This office was put into service during January 1914, and is the largest and most modern long distance exchange in the world. The switchboard consists of more than 200 operators' positions, occupying two entire floors in a large fireproof building, and handling approximately 13,000 outgoing and incoming calls per day. An interesting feature consists of a pneumatic tube system by means of which tickets containing information in regard to calls are carried from one part of the office to another. Much interest was taken by members of the excursion in the provision made by the company for the welfare of the operators.

Through the courtesy of Rear-Admiral N. R. Usher, Commandant, 90 members made an interesting trip to the Brooklyn Navy Yard under the guidance of W. P. Hayes and E. S. Cooley. The tug Powhattan had been placed at the party's disposal, and the visitors were conveyed from the foot of East 23rd Street to the Navy Yard, thus making a novel approach. They were shown through the machine shop, boiler shop, foundry and power house and noted the various points of interest. Three submarines were also seen in drydock and a comparison with the original Holland submarine, mounted in the yard, showed what strides have been made in developing this type of vessel. The dreadnought Wyoming, of 26,000 tons burden, was then inspected. This has 12-in. rifles, 50 ft. in length, and its engine rooms are equipped with turbines developing 33,000 h.p. showing great compactness of installation. The dreadnought Rivadiva, just completed by the Cramp Shipyards for the Argentine Republic, was viewed as it went into drydock. This vessel is armored with twelve 12-in. rifles as well as numerous smaller caliber guns, and is fitted with a torpedo net. It develops a horsepower of 39,500. The party returned to Manhattan on the same tug. The various points of interest at the Navy Yard were explained by Lieut.-Com. S. H. R. Doyle, supervising the construction of the new dreadnought Arizona, by Lieut. C. A. Blakeley, in charge of

the machine shop, and by Lieut. C. W. Nimitz, the naval expert on Diesel engines. Lieut. H. G. Shonerd acted as the general guide.

On Thursday afternoon a party of 135 visited the studio of the Biograph Moving Picture Company on 175th Street. The party was divided into three groups and shown through the building by Mr. J. J. Kennedy and his assistants. The building is five stories in height, of reinforced concrete and fireproof construction. The laboratories for developing, reproducing, etc., are on the top floor, as is also the large daylight studio with its immense glass dome, for use in fair weather. A number of different scenes can be taken at one time in this room. The artificial light studio is located on the third floor and is arranged for four stage settings. At the time of the visit three of the stages were in operation, and the visitors saw several rehearsals and the final production. Each scene is rehearsed until it can be carried through in the definite length of time allowed for the act, and two reels are taken of the finished product, one of which is preserved and the other developed. The light effect is produced by the mercury vapor lights, with tubes approximately four feet in length and arranged in batteries of 24 to 30. The batteries are on racks which can be shifted around in different positions and adjusted to produce practically any light effect required. The studio is working 20 hours out of each 24, as the demand for reels is greater than the company can supply, even with its force of 300 or 400.

On Friday morning an instructive trip was made by about 60 members to the United Electric Light & Power Company's generating station at 201st Street, J. H. Lawrence acting as conductor. Buses furnished by the company conveyed the members to the power station, and two hours were spent in inspecting the various equipment. This power house represents the latest type of power station design in this vicinity and is unique in that the main units and auxiliaries are all turbine driven. The plant will have a capacity of 120,000 kw., three units of 15,000 kw. each being at present in operation. There are 32 boilers of 650 h.p. each, with provision for 40 more if necessary. All of the boilers are equipped with the Metropolitan cinder catcher, which has proved very successful in this work. Luncheon was served to the visitors in the plant by the company.

Small groups also visited the Bureau of Municipal Research on Wednesday afternoon and the McCall Corporation on Thursday morning, R. V. Wright acting as guide in the latter case. It was expected that the members would have the opportunity of inspecting the S. S. Lusitania, but this proved to be impossible.

WEDNESDAY AFTERNOON SESSION

SYNOPSIS OF PROCEEDINGS OF AFTERNOON SESSION OF DECEMBER 2, 1914, OF THE ANNUAL MEETING

FLOOR SURFACES IN FIREPROOF BUILDINGS

BY SANFORD E. THOMPSON, NEWTON HIGHLANDS, MASS.

Member of the Society

No one type of floor surface is adapted to all conditions, and having selected the proper type, the choosing of the materials and the manner of the construction govern to a large extent the durability of the surface.

It is the purpose of the paper to discuss briefly the different kinds of floor surfaces; indicate the types of construction which may be selected under different conditions; give approximate costs of various floor surfaces; describe tests and investigations of granolithic construction made in connection with the buildings for New Technology (Mass. Inst. Tech., Boston, Mass.); and present recommendations for granolithic construction.

Summarizing the discussion on the characteristics of floors:

Granolithic Trowelled. As ordinarily laid in buildings, granolithic or concrete surfaces are subject to dusting and under heavy traffic, such as trucking, are liable to serious wear. On the other hand, experience with first-class construction and tests of actual floors show that it is possible, by proper selection of the aggregates and expert workmanship, to reduce the dusting to an insignificant amount and to produce a surface hard enough to stand even severe wear. The chief objection to concrete or granolithic surfaces for offices, drafting rooms, classrooms, laboratories, etc., is that it is hard on the feet for men standing all day, tends to break tools dropped upon it, and is not adapted for attaching seats or other furniture. In certain colleges, however, concrete floors are used widely and are highly recommended. In one instance the men complained of coldness and hardness where the floor was laid directly on the ground, whereas, where there was a warm basement underneath no objection was raised. Cost, 5 cents to 7 cents per sq. ft.

Granolithic with Ground Surface. Experimental surfaces, together with laboratory tests made as a check, show that a pleasing surface, approaching terrazzo in appearance and fully as durable under foot traffic, can be obtained by placing granolithic with

scarcely any troweling, and then grinding the surface just enough to expose the grains of sand and stone. It is suggested that this grinding might remove the objection of dust previously referred to. The extra cost is estimated not to exceed 3 cents per sq. ft.

Linoleum. The hardness and noise characteristic of granolithic finish are overcome by covering the surface with Battleship linoleum. The linoleum should be stuck firmly to the granolithic surface and preferably a cove base should be run around the room and sills provided at entrances so that the surface of the granolithic will be flush. In this way the edges are prevented from fraying. The life of first-class quality Battleship linoleum, if edges are not frayed, is probably from 15 to 30 years, depending upon the amount of travel. The cost, allowing for the better finish required on the concrete, is substantially the same as for a single floor of birch or maple. Cost, 18 cents per sq. ft., including 3 cents per sq. ft. for $\frac{3}{4}$ in. layer of mortar.

Hardwood Floors. Floors of maple, birch, beech, oak or long-leaved Southern pine, are used most largely for offices, classrooms, or lecture rooms, and in many of the older colleges for laboratories and halls. A wood surface, however, is not usually considered entirely satisfactory either in general appearance or in wearing qualities. There are various methods of laying hardwood floors. For classrooms a single thickness of maple or birch nailed to sleepers with cinder concrete between should be satisfactory. Another type of construction is to use patented metal screeds imbedded in the base concrete, and nail the floor boards to splines in the screeds. For rooms subjected to heavy traffic, 2-in. or 2 $\frac{1}{2}$ -in. plank may be placed underneath the hardwood floor. Cost 18 cents to 25 cents per sq. ft. based on a price of \$45 per 1000 board measure.

Terrazzo. This is made by spreading upon the base concrete a mixture of neat cement and marble chips and grinding the surface to a depth sufficient to cut into the stones and expose them on their largest diameters. The joints between the particles, being of neat cement, are hard and even more durable than the pieces of the marble themselves.

Terrazzo is largely used, especially in the newer office buildings and in institutions, for corridors and halls. It also is satisfactory for lavatories, although more expensive than granolithic. It appears from the author's investigations that for both of these uses concrete with a ground surface can be substituted at less cost and with satisfactory results. Cost, 19 cents to 24 cents per sq. ft.

Magnesium Composition. Suitable for offices, class,

Abstract of paper presented at Annual Meeting, December 1914. Complete paper may be obtained without discussion, price 5 cents to members; 10 cents to non-members.

lecture and drafting rooms, and laboratories. If carefully laid it wears satisfactorily. Any imperfections are apt to show within the first year. It is more resilient than granolithic, less noisy, and furniture can be screwed directly to it. Colleges have used it extensively, especially for certain laboratories, and Cooper Union in New York City have many such floors proving satisfactory. Cost, 20 to 24 cents per sq. ft.

Essentials of Granolithic Construction. Aggregates should contain no dust but should consist chiefly of particles ranging from $\frac{1}{8}$ in. to $\frac{1}{2}$ in. in size.

Proportions with first-class materials should be one part cement to two parts aggregate.

This mixture should be of such consistency that it will not flow but will hold its shape in a pile without settling.

A perfect bond must be made with the base concrete either by laying the granolithic before the concrete has set, or else roughening surface and providing a bond of neat cement paste.

Laying must be done at moderate temperatures, avoiding temperatures below 50 deg. Fahr.

Troweling should be thorough but no excess water should be brought to the surface. A hard, dense surface rather than a smooth, glossy surface should be the aim.

The surface should be kept wet for at least ten days to two weeks after laying.

In General. The paper contains also a table of approximate costs of the different floor surfaces, which are given more in detail than mentioned in the above summary. There are also a set of specifications for laying granolithic finish on set concrete and specifications for grinding granolithic surfaces.

DISCUSSION

In presenting the paper the author said that good granolithic floors were being built which will stand very severe traffic and that will dust only to a very small degree. The five principal requirements are: Materials, proportions, bonding, methods of laying, and treatment of surface, if any. Use coarse material with the cement, avoiding fine sand or stone with fine particles because this rises to the surface in troweling. Use a comparatively dry mix that will have to be put on with the aid of tampers. There are certain compounds on the market that will prevent dusting, but if the right materials and workmanship are employed, so little dusting will occur as to do no harm for ordinary purposes.

For durability it is best to lay the floor surface along with the base concrete. This is often almost impracticable and tests have proven that a good bond can be obtained on old concrete with the proper treatment. Special attention is called to the specifications given at the close of the paper to laying granolithic in cold weather.

ROSS F. TUCKER. So much difficulty exists in securing a good wearing surface for granolithic that hardwood is preferred for all purposes, particularly where operatives have to be on their feet.

L. C. WASON. The cost of granolithic quoted by the author is too high by 10 cents per sq. ft. There is also a difference of $3\frac{3}{4}$ cents per sq. ft. between hardwood floors 2 in. face by $1\frac{1}{8}$ in. thick as against $3\frac{1}{2}$ in. face by $\frac{7}{8}$ in. thick. Magnesium composition is also laid at a third less than quoted.

It has been found that factory operatives claim that lameness and fatigue are caused by granolithic floors being better conductors of heat and cold. This has been overcome where floors are cold by wearing heavy shoes.

Nalcedo, another material composed of asbestos, portland cement and sand, is giving better results than screed for wood floors.

For a granolithic floor no particles should be used smaller than those passing a No. 30 sieve, and hard rock which will withstand abrasion should be used, without any sand, the proportion being one to two. It is also pointed out in bonding to old surfaces that a thin top, i. e., $\frac{3}{4}$ in. or 1 in., is more likely to come loose than a thicker one.

Commenting on Appendix No. 1, a multiple pick is cheaper and requires a less experienced workman than a bush hammer.

Dilute muriatic acid is unsafe unless the concrete is dense, otherwise it is likely to soften it.

The mixture should not be limited to granite, as traps and gravel give good results. A stiff mortar gives best results, although a different consistency should be used, depending on whether the base is fully set.

Much better results can be obtained by using a wood float than a steel trowel. Specification should read, Float granolithic surface as soon as it begins to stiffen. Commenting on Appendix No. 2, better results can be obtained with wet grinding than with dry.

G. S. WALKER. There is almost certain to be trouble with granolithic if the base is allowed to set and an attempt afterward made to bond the surface to it. This is due to the shrinkage rate being different. They should always be laid together.

WALTER S. TIMMIS. There is a very serious defect in wood floors in fireproof buildings, that of springiness. This was more apparent in the earlier buildings where floors were laid directly on the arches, but even in recent buildings it occurs, owing to care not being exercised in bringing the cinder fill to the top of the screed. Dry rotting of screed also often takes place, especially when the floor is laid before the cement is dry. On granolithic floors, the difficulty in getting a smooth surface and no dusting is due to the troweling not being done at the psychological moment.

GEORGE P. HEMSTREET in a written discussion, called attention to another form of asphalt floor for fireproof buildings, streets, piers, warehouses, etc., used for many years, viz., asphalt blocks composed of hard crushed stone and about 7 per cent asphaltic cement formed under hydraulic pressure of various sizes and forms. These are laid in cement mortar with joints grouted. The surface is smooth, resilient, non-slipping, dustless, sanitary and not easily marred. The cost is \$1.50 to \$2.50 per square yard.

THE AUTHOR, in closing the discussion, agreed with Mr. Wason's description. Regarding bonding new to old, the

best answer is the fact that it has been done with good results due to the neat cement applied to the roughened surface which seems to overcome the theoretical difference in expansion and contraction.

REINFORCED CONCRETE FACTORY BUILDINGS

BY F. W. DEAN, BOSTON, MASS.

Member of the Society

The reinforced-concrete factory building is in considerable favor at present and is likely to be increasingly so. It is fireproof and gives the maximum resistance to fire. Other merits are the possibility of greater window area over the regular mill construction, the light color of the ceilings and adaptability for heavy floor loads without requiring narrow bays.

There are two general types of floor construction, one with beams, the other with smooth ceilings known as the mushroom construction. For factories, especially when lineshafts with large pulleys are used, the beamed construction is preferred, while for storehouses and machine shops with light motor-driven machines the smooth ceiling is better. The strains in the mushroom system are more uncertain but, in practice, no inconvenience or risk arises.

In the beam system the building as a whole is encased in forms, while under the Ransome or "unit" system the columns and beams are cast separately on account of which it is claimed, probably with truth, that the latter method is cheaper.

It is claimed that owing to the rigidity machines can run faster with less vibration than in a mill construction building. This is probably true, but speed is dependent on other things than the rigidity of the building, such as the limitation of the machines themselves, personal skill and accompanying processes. The larger columns necessary are a disadvantage and in textile mills are intolerable. Sometimes steel columns encased in cement are used.

Concrete floors always are a source of trouble on account of wearing unevenly, especially under heavy trucking. Coarse crushed granite in a rather dry cement has been unsuccessfully tried, and the various compositions for preventing wear are so expensive as to necessitate their being used sparingly.

A disadvantage in concrete buildings not occurring in mill construction is the necessity of working out in advance many things in connection with placing machinery, wires, pipes, etc., as well as the difficulty of correction afterward. On the other hand, if planned for, many sockets, inserts and angles for hangers can be placed during construction.

The dusting of floors is a difficulty especially where

the dust affects the product. A wood floor is therefore often required and this is preferred as well by operators because the concrete is cold. The best way to lay a wood floor is to place thick planks kyanized or otherwise treated to prevent rot, with the top floor nailed to the planks. This produces a floor of the necessary stability.

The exterior can be treated to obliterate the form marks in different ways by tooling with a pneumatic tool, or washing with a marble, cement or other wash. There is no limit to the ornamentation and beauty that can be given.

Sprinklers are needed as the contents are inflammable. In one case the furniture made a fire that cracked the cement off the reinforcement. The Salem fire showed the importance of abandoning overhanging roofs, wood window frames and sashes. In this fire, however, the brickwork offered effective resistance, and with the building walls extended above the roof a mill construction building with metal frames and sash with wired glass will usually withstand an external fire.

The difficulty of demolishing a building tied together in all directions with steel rods encased in material that has become as hard as rock is interesting to consider. As to cost, while it has often been stated that reinforced concrete can be built as cheaply as mill construction, the writer's experience is that the former costs fully 20 per cent more.

It is common practice to fill in the panels with brick, because it is cheaper and looks better. The latter is a matter of taste, the former is questionable, and in Germany, where reinforced concrete has been carefully investigated, such construction has not been found advisable.

Where fire-proof construction is paramount and where heavy floor loads are to be sustained, reinforced concrete buildings are desirable; but if these requirements do not exist and the location is isolated, it is hard to justify the additional expenditure.

In presenting the paper the author said that in the Salem fire the behavior of the Naumkeag mill buildings had opened the eyes of engineers because these buildings took fire in consequence of their overhanging wooden roofs and wood window frames, but more especially because one old brick warehouse where the roof was completely protected by a brick parapet stood the fire as well as certain concrete warehouses.

DISCUSSION

GEO. C. STONE contributed a written discussion in which he said the author had a seeming prejudice against the use of reinforced concrete for factory buildings and insisted that with a fair comparison of advantages and especially of wide bay construction, which is readily obtained in concrete buildings but which is quite an item of expense in mill construction, in that it requires steel beams, the cost of the two types is nearly equal or even in favor of reinforced

concrete. Besides, reinforced-concrete construction is fire-proof. He amplified the good features of reinforced concrete (over mill construction) mentioned by the author, in the following respects:

The floors of concrete are in themselves sufficiently waterproof to prevent water passing through into the story below. Larger window area can be obtained even up to 85 per cent of the gross wall area.

An initial expenditure of $\frac{2}{3}$ of one cent per sq. ft. of ceiling area will provide for a liberal placing of inserts which will make the building perfectly elastic for the entire rearrangement of any ordinary kind of overhead machinery.

Additional floor surfaces are mentioned, i.e., plain troweled cement, wood top floor on screeds in cinder cement, wood block on end, terrazzo, linoleum and tile, each with its advantages peculiar to itself.

Regarding architectural effects, it is suggested that more attention could be given to the jointing between the separate pourings, treating these from a design point of view and getting away from the habit of considering the building as a monolith instead of a series of gigantic blocks of artificial stone laid one upon the other and doveled or otherwise fastened together, as it really is. There is no limit to the ornamentation and beauty that can be given, this being dependent only on what is justified for that purpose.

Regarding the fireproof features, attention is called to one of the Naumkeag storehouses in Salem which is of reinforced concrete construction with wired glass windows and was not mentioned by the author. This came through the fire with its glass windows buckled but with its frame uninjured and its inflammable contents unharmed.

J. P. H. PERRY presented a written discussion in which he said he thought the author to be unfair to the recognized merits of properly designed and executed reinforced concrete construction for industrial purposes. In view of the tremendous fire loss in this country, it seems unwarranted to recommend non-fireproof or slow-burning construction whenever the owner can possibly afford a fireproof building, especially in view of the difficulty of securing high-class timber and the difficulties with dry-rot.

A number of plants, notably printing houses, have obtained greater efficiency from reinforced-concrete buildings because of, first, their less vibration, and second, the fact that shafting remains permanently true. Upkeep has also been less.

Steel columns have been used in only a small percentage of buildings. The octo-spiral columns of the Hoadley type avoid the waste space occupied by square columns and are better in appearance.

It is too severe to claim that concrete floors "cannot be uniformly dense or hard and that they wear unevenly." The many millions of feet of such floors giving reasonable satisfaction is an answer to this. Some bad floor work is, of course, done and good floors are damaged by severe trucking. Floor hardening materials help, but wax driven into the floors does very little to improve the quality of first-class jobs.

In practice, the difficulty of attaching shafting is very small. At a small added expense, extra sockets of many different forms, now well commercialized, can be frequently located to provide fastenings when changes are required.

An electrically driven portable drill has proved efficacious in tapping holes in the concrete in any part at small expense.

Contrary to the author's statement, the majority of chocolate factories in the country are using reinforced concrete with complete satisfaction.

Rarely are board marks removed, but it can be done without a considerable expense by tooling, or the exterior can be stuccoed or veneered with brick or tile. The general appearance depends mainly on the proportions of the structure and the simplicity of the ornamentation plus some wash or paint treatment to bring the exterior to a uniform color. A critic's opinion will be favorable if he will consider the concrete as concrete, not as brick or other material.

Brick curtain walls are often introduced to get what some consider a more pleasing effect. Sand blasting has not usually proven satisfactory because it tends to pick out the soft spots. A cold chisel worked by hand is better.

The author overlooks the four-story reinforced concrete warehouse of the Naumkeag Mills in Salem which withstood the fire without an interior sprinkler going off. The storehouse he refers to was formerly a gasometer without widows and with a newly laid asbestos roof, but with a wood skylight at the peak. The warehouse was undamaged, due probably to a recognized phenomenon, viz., the collection of cold air in spots. All the other mill constructed buildings of the Naumkeag Mills which were recognized by the Mutual Insurance Companies as one of their best risks were destroyed, many brick walls collapsing.

There have been many instances of a fire in a mill construction building where the sprinkler equipment has been cut in two by the early blaze and the rest of the plant entirely destroyed as a result.

Removing concrete buildings has, contrary to the author, been worked out economically and efficiently.

Many competitions in the metropolitan territory have shown an increase over mill construction of 8 per cent to 15 per cent, but if the same floor loads and column spacing are allowed, the cost would be about equal.

The question of adhesion of concrete to bars has been thoroughly demonstrated. With deformed bars at least the stresses assumed in design will be distributed and obtained in actual work. A laboratory test proved that if a commercial smooth bar was milled smooth the bond was materially reduced.

WALTER F. BALLINGER took exception to using the circular storehouse of the Naumkeag Mills as a sample of the fire-resisting qualities of mill construction. Regarding comparative costs, there have been instances where the difference in proposals has been as low as six cents per sq. ft. between an entire reinforced-concrete building and one of the slow burning or mill construction; in certain circumstances where supply of material is at hand and where railroad sidings exist reinforced concrete is less expensive. In the majority of cases, insurance and upkeep considered, reinforced concrete is usually more economical.

Reinforced concrete permits a small number of posts and greater spans and with the use of the spiral type of column, it need be no larger than yellow pine. It is practicable to build a span as long as 60 ft. This has been done at an actual saving over steel fire-proofed, and in one case was even cheaper than having the steel structure unprotected.

It is known that machinery will vibrate less in a reinforced-concrete building, and this has actually resulted in saving of electric current due to the machinery running more true.

WALTER S. TIMMIS: Further objections to mill construction are, the difficulty of getting timbers for long spans properly seasoned, the time it takes to get timbers, and the shrinkage of beams away from the girders and the large amount of vibration. Except in buildings over eight stories, sizes of columns need be no larger than required by cities of the first class for steel columns fireproofed. The machinery layout and provision for changes merely resolves itself to putting into the concrete sufficient inexpensive inserts. Lay the plant out first and build the building around it. Most everyone believes in sprinklers in any type of construction.

THE AUTHOR said in closing that one object in writing the paper was to create discussion and that he was appreciative of the contributions which so well accomplished this.

MEASURING EFFICIENCY BY H. L. GANTT, NEW YORK CITY

Member of the Society

The author contends that the attempt of the accountant to furnish the financier with easily obtainable measures of efficiency has not only been a failure, but that the attempt to use as measures of efficiency the criteria which he has provided, is one of the most serious causes of inefficiency with which the practical manager has to contend.

Fortunately for industry at large, the first fallacy, namely that it is necessary to have low wages in order to get low costs, is rapidly falling into disrepute; but the second, namely, that the ratio of non-productive to productive labor is a measure of efficiency, is still strongly and almost universally held by accountants and financiers. This fallacy, on account of its widespread acceptance, is responsible for more inefficiency than almost any other cause.

Inasmuch as the object of increasing the efficiency of an industrial operation is to reduce the cost of that operation, the only real measure of the efficiency with which the operation has been performed is found *in the effect on its cost*.

The only reliable indication, then, of the efficiency of a plant is furnished by the detail shop cost of the operations performed.

Before any great progress in the solution of our industrial problems can be made, the two fallacies referred to must be abandoned, for they not only directly hamper the operating executive in his efforts to promote efficiency, but impose upon him conditions that make it almost impossible for him to secure the proper coöperation of his employees, and are thus indirectly

the cause of much of our industrial unrest. In reference to these two fallacies the author says:

With the growth of competition within the last 20 years the necessity for some knowledge of costs became evident, and the manufacturer turned to the accountant for a system of finding costs.

The present system of railroad accounting had been developed, and certain ratios accepted as measures of efficiency of operation; notably among them the ratio of operating expense to total income.

Being accustomed to having the managerial efficiency of railroads expressed by a simple ratio, the financier demanded a similar simple measure of the efficiency for an industrial plant. The cost accountant promptly gave him what he called the ratio of "non-productive" to "productive" labor, which he said should be low for good management. By "non-productive" labor he meant salaries of all kinds, and all other labor that could not be charged directly to an order, including miscellaneous labor such as watchmen, sweepers, truckmen, etc. By "productive" labor was meant simply that labor which could be charged directly to an order.

While the ratio of operating expense to total income may be a fair measure of efficiency in a transportation company, the ratio of "non-productive" to "productive" labor is not only not a fair measure of the efficiency of operation in a manufacturing plant, but is often exactly the reverse.

To my mind the widespread use of this ratio as a measure of efficiency, has been more effective in producing inefficiency than any other single factor, except the oft-repeated statement that you must have low wages if you would have low costs. Until these two fallacies are absolutely discredited, we cannot expect a solution of our most serious problems.

Of these two fallacies, the second, namely, that you cannot have high wages and low costs, seems to be yielding gradually to the overwhelming mass of evidence against it. So many cases are now on record where the industrial engineer has increased output, raised wages, and at the same time lowered costs, that only those who are too conservative to investigate are still holding on to the old theory. Better still, many employers have shown the courage of their convictions by adopting a scheme of management for the increase of output and the reduction of costs, which they are perfectly well aware will make a decided increase in wages. With evidence of this kind at hand, it is safe to say that this fallacy will before long be entirely discredited. On the other hand it must be fully understood that something more than a simple increase in wages is necessary to increase output, and if nothing is done but to increase wages we are sure to get higher costs.

The other fallacy, that the ratio of "non-productive" to "productive" labor is a gauge of efficiency, is so firmly rooted, however, that it is hardly to be expected that it will yield in the near future.

In speaking of cost systems the author states that the essential elements of a reliable system are a knowledge each day of

- a what was done the day before
- b who did it, and
- c what was paid for it

It is comparatively easy to get a set of returns purporting to give this information, but the real difficulty comes in knowing whether these returns are correct or

not. The only sure way of judging of the correctness of these returns is to know beforehand

- a what should be done the next day
- b who should do it, and
- c what should be paid for it

If work can be planned on these lines the basis is formed for a real system of management. In fact, he says:

Even in the most poorly run business, some attempt, either consciously or unconsciously, is made to control work on these lines. Moreover, we generally find that the more nearly the above ideal is approached, the most successful the plant is, and all will admit the desirability of such a system if it can be established without excessive clerical work.

When it is realized that the installation of such a system seldom results in an increase of output of less than 25 per cent, and often as much as 100 per cent, it is easy to see that the additional clerical work cuts but little figure. As a matter of fact the clerical work needed to operate the best systems of this type is decidedly less than that needed to operate any of the standard cost systems put in by chartered accountants.

It must be borne in mind, however, that during the process of installing the new system and training the employees to operate under it, the old system must be continued; and not until each function performed by the old has been taken over by the new can we drop the old entirely.

During the process of installation, therefore, we must to a large extent operate two systems. This necessarily runs up the ratio of "non-productive" to "productive" expenses, and the accountant lifts up his hands in horror at the expense the new system is running them into. If at the same time the new system is successful in reducing the "productive" labor, the ratio is still higher, and the "showing" is still worse, even though the total cost is less. I therefore repeat that the first step to be taken before introducing a modern system of management is to eliminate the ratio of "non-productive" to "productive" labor as a measure of efficiency.

The elimination of this ratio as a measure, and the establishment of the fact that total cost is the only reliable guide, will do much to pave the way for an improved system of management. How is this to be accomplished?

The first step is to revise our ideas as to the functions of a cost system. In the past the principal function of a cost system, besides indicating a limiting selling price, has been to enable those in financial control to criticize those operating the factory. These criticisms are usually from one to three months late, and are so general in their character as to afford, as a rule, no guide whatever by which the superintendent can be governed. Such a system is too often most highly prized for its worst defect, namely, that it enables those in financial authority to criticize without taking any responsibility whatever for showing how to do better.

If, instead of making the function just described the prime one, we raise to equality with it, a function which requires the system to furnish promptly, day by day if necessary, exact information of what has been done and what the expenditure has been, we shall find that its most valuable function becomes, not finding costs, but furnishing the superintendent with information which helps him to reduce costs.

In other words, before we can expect to get any great benefits from the newer managerial ideas, we must readjust our ideas of the functions of the cost accountant, *who must become the servant of the operating executive as well as of the financial executive.*

As long as the cost accountant is simply a critic, he may be called "non-productive," but when he furnishes the superintendent with prompt information which enables him to reduce costs he becomes "productive." Prompt detail information of what is being done each day, furnished in such manner as to be readily compared with what has been done, and what can be done, is the best method of measuring efficiency.

DISCUSSION

HARRY E. HARRIS contended that the annual monetary return for the amount invested is what interests those responsible for any undertaking. This cannot be measured by any arbitrary rule of accounting, nor by a comparison of the earnings of the wage earner. Neither can it be judged by individual costs of separate operations without consideration of overhead factors, since it is possible to show by cost records a very high increase of efficiency and still operate under an increasing loss. Efficiency, taken in the sense of manufacturing at a low direct labor cost, is not always synonymous with economy, and therefore is not always expedient.

Rather than depend upon day-to-day costs, which, while valuable to a certain extent, are expensive to maintain, the writer preferred that efficiency should be measured periodically, by taking the total productive costs, *i. e.*, direct and indirect labor, plus salary expense, material, a portion of the cost of new equipment, etc., together with the total sales value of the articles produced during some period, and comparing their ratio with similar ratios taken at previous periods.

FRED J. MILLER said that the percentage of operating expense is of no importance by itself; a low percentage may mean a high total cost of product, or a high percentage a low cost of product. In a factory where the work is done mostly by hand, with low cost fixtures or tools, labor costs will be high, and operating expense or overhead charges low. Suppose, however, that automatic machines are devised for doing this work, and that almost no human agency is required for their operation. Under such conditions the percentage of operating expense might rise from, say, 20 to 1000 per cent, if based upon labor cost, yet under the second condition the total cost presumably would be lower. It cannot be too often insisted upon that the term "non-productive labor" is a misnomer; that there is no such thing as non-productive labor in a well-organized and well-managed industrial establishment. The work of clerks, draftsmen, pattern makers, tool makers, etc., is usually productive labor in the highest sense.

H. K. HATHAWAY said in elaboration of certain details referred to by Mr. Gantt that under scientific management, not only is the ratio between direct and indirect labor increased as a result of lowering the amount of direct labor through the elimination of wasted effort, but by transferring to others many of the things which the workman formerly

did himself, as, for example, the grinding of tools, fixing belts, planning the work, etc. This work is just as productive as if done by each machinist himself, although it is difficult to charge it directly to the various jobs to which it applies. Those who attach such great importance to the ratio of indirect to direct expense should consider that the more inefficiently those whom they class as producers do their work, the lower will be their ratio. The only satisfactory means for measuring efficiency is a comparison of work done with a task set, based on standardized conditions and accurate time study.

HENRY H. SUPLEE thought that in determining efficiency it was frequently done from the wrong end, that is, after operations were conducted, instead of with some reasonable degree of truth beforehand. He commended the principle involved in the simple methods of the man who manufactured clothing in New York. He made what he called "pants," and his method of reasoning was as follows: "I can sell these for \$2.50 a pair. If I cannot sell them for that, I cannot sell them at all. I must make 50 cents profit on each garment, or I do not want to make them at all." He took out his profit first. That left \$2 a pair for manufacture. Then he figured how many pairs an operator could make in a day, and how much wages he would have to pay the operator at the union rate. He figured his overhead charges, rent, clerk hire, etc., and after deducting all his expenses of this character, determined how much he had left to buy the materials, and the quality of the materials he purchased was covered by the amount at his disposal.

W. A. POLAKOV said that the quintessence of the shortest paper presented at that session, but on the biggest question, is the statement that the most valuable function of the management is not finding costs, but furnishing the superintendent with information which helps him to reduce costs. Information furnished by accountants is like that which tells us why a patient has died. What is needed is a diagnosis from which the management can learn before everything is over, what, when and how the work shall be done, and therefore how much it will cost.

It had been the good fortune of the speaker to work for and with the author, and as he was now applying the principles of Mr. Gantt to his own business of managing central stations, he had invariably found that an unprecedented increase of efficiency and reduction of costs is possible, if the operating force is supplemented by a body of "non-producers" constituting a planning department, whose office is to teach the producers what, when and how to do.

STANDARDIZATION IN THE FACTORY

BY CARL BENNETT AUEL, EAST PITTSBURG, PA.

Member of the Society

A brief outline is given in this paper of the ways and means employed by a large electrical establishment in their work of standardization.

Drawings: It was formerly the custom to make all drawings as complete and self-contained as possible.

Opposite each item a note was placed specifying the material required to manufacture it. When drawings for new apparatus were made and any of the old parts could be used, these parts were shown again on the new drawings in complete detail, so that the workmen would not have to refer to any other drawing. This method was found to involve more and more a duplication of drafting and clerical work and the scheme of making elemental drawings with one piece on a drawing was next considered; but, while this insured accuracy in duplication, it had the disadvantage of too many drawings to handle. A compromise arrangement was therefore adopted, consisting of a natural grouping of pieces or parts on a single drawing. Each piece is assigned an item number and a list of the material involved is located conveniently on the drawing arranged numerically according to item numbers as shown in Fig. 1.

Fig. 2 shows a standard drawing of a line of wing nuts, arranged, however, in such manner that the various items may be cut into cards and issued to workmen who can attach them to the belt shifters of their machines when working.

Manufacturing Information: All apparatus and parts are built to so-called manufacturing information, which consists of a specification setting forth the drawings to be worked to, with a list of the various kinds and amounts of material required. Copies of such portions of these specifications and drawings as pertain are issued to all departments having work to do in connection with an order, and these specifications are closed when the order is completed.

Specifications and Shop Processes: When either the quality or the importance of the items warrant, specifications are carefully prepared for the purchasing and the inspection departments who use them in the purchase and the subsequent inspection of such materials. Another equally important line of work consists in the development of manufacturing processes and formulae which, when standardized, are recorded in permanent form and issued to the various manufacturing departments involved. In this way uniformity in product is assured, there is no needless repetition of lessons or experiences previously learned, and the company is made independent of any individual's knowledge.

In the paper is reproduced a set of specifications for cold-drawn steel, the general arrangement of which is in accordance with the standards of the American Society for Testing Materials. An example is also shown of process specifications.

Visible Production Charts: In Fig. 3 is shown a form of production chart, or load diagram, used quite generally throughout the works. Curve *a* is the daily total of unfilled orders, machines or pieces obtained by adding to the total on hand, the number received each day and subtracting the number shipped. Curve *b* shows the maximum possible out-

put of which the department is capable in a month. Curve *c* is the desired output for the same period. While these two latter are both straight lines, their

FIG. 1 MERCURY RECTIFIER OUTFIT, DOUBLE FLANGE FOR TRANSFORMER PORCELAIN BUSHING

shape could of course, be altered, though with a loss in simplicity. Curve *d* indicates the actual output and a comparison between it and curve *c* tells whether

having certain standard sizes and kinds of materials, the first steps in standardization naturally fell to the drafting department. Later a standards division of the engineering departments and a Standards Committee were created, whose functions are the standardization of existing materials and parts. The work of the Standards Committee has been varied in the extreme, such matters having been successfully handled as punched circular washers, thumb and wing nuts, oil-hole covers and hinges, furniture, anchor holes in bearings, wood handles, sizes of tap drills, stresses in eye-bolts, thickness of babbit in bearings, liners, trucks, etc.

Cutting tools have been standardized as well as die and jig parts, die shoes, punches and punch holders, punch and stripper plates, jig boxes and bushings, drill press shanks, etc. Endeavor has been made to place on working drawings the allowable variations from drawing dimensions for standard parts.

The method which has been adopted consists in placing the nominal dimensions first, followed by the limiting dimensions in brackets: thus $41.4 \left\{ \begin{matrix} 4.251'' \\ 4.248'' \end{matrix} \right\}$. There has, however, been a certain preference expressed for a slightly different method, namely

$$41.4 \left\{ \begin{matrix} '' + 0.001 \\ '' - 0.002 \end{matrix} \right\}$$

but the objection to this method is that whoever uses

FIG. 2 SECTION OF STANDARD DRAWING OF A LINE OF WING NUTS

the department is working up to its schedule or falling behind. Curve *c* is that of actual daily deliveries.

Standardization: Owing to the obvious need for

these dimensions must add or subtract the allowance each time same are used.

Allowances for Expense Materials: The monthly

consumption of various expense materials, such as oils, greases, waste, incandescent lamps, janitor's supplies, etc., has been estimated for the individual manufacturing departments, based on normal production. From these investigations, allowances have been set on each item and a department is permitted to draw from the storehouse on requisitions up to its allow-

FIG. 3. LOAD DIAGRAM

ance. Anything in excess must first receive the approval of the superintendent of the department.

Handling Materials: Considerable study has developed economical means for handling smaller materials, as for example misprint cloth bags in place of paper wrappings; for larger material metal tote boxes without wheels or with telescoping wheels. For transporting, standard gage steam and narrow gage electric storage battery cars and hand, platform lifting and electric storage trucks are used. These latter have proved very profitable as labor savers. A central oil storage warehouse has been established with pipe lines to each building. A further development will be the delivery within the building of oil from an electric truck, and this method could be worked out advantageously for inter-department delivery of material. Mail is handled from a central post-office through pneumatic tubes to the principal departments.

Safety Methods: Well-defined steps have been taken for the systematic introduction of safety methods and devices. A supervisor of safety appliances was appointed and a monthly appropriation issued to cover the cost. No new tools are erected nor old tools replaced without adequate safeguards, by which means dangerous tools or equipment are gradually eliminated. An analysis of the accidents for the past year shows but three-tenths of 1 per cent to have been caused by the absence of safeguards. By far the largest percentage, namely, 21½ per cent, were due to the carelessness of the injured themselves, so it means a campaign of education must be undertaken. This is being accomplished in several ways as for example, through the medium of small yet prominent Safety First metal plates which have been placed in a prominent position on every machine. Signs bearing this and similar legends have been recently standardized by several national societies, among them Founders, Manufacturers, Metal Trades, and Electric Light. Lectures are also given to workmen which are repeated to the same persons at intervals of six months.

Inactive Materials: All stock ledgers are regularly scrutinized by the storekeeping department and slow-moving or inactive items submitted to a materials disposition department that investigates not only the cause of the inactivity with a view to preventing a recurrence, but at the same time endeavors to dispose of the material to the best advantage.

DISCUSSION

H. B. LANGE said in a contributed discussion that to appreciate the field of opportunity for standardization it is to be noted that many works organizations maintain engineers who make this work their sole function. It has been often demonstrated that on repetitive work low costs can be accomplished by reducing all product to a unit basis without reference to the final assembly. Where working within limits of allowable variations it would seem advisable to draw one part only on a subdivision of a drawing sheet preferably of letter sheet size—with a separate part list and an arrangement drawing giving the assembly information. Proper filing and classification of prints of drawings assists in selection of parts already in use and revealing parts of similar character which might be consolidated for standard adaptation. The cost of drawings is negligible compared with accrued benefits. Mounting prints on strawboard and keeping them filed when not in use is economy. Standardization can be furthered by a showing on a letter size sheet the part with a list below of the differing dimensions. This is especially applicable to purchased parts used, and these bound together give a simple and condensed means of imparting essential information. In fact this same size sheet and the letter dimension scheme extended to parts made in the shop is worthy of consideration.

L. D. BURLINGAME said the paper illustrates the transition from the old-time method when the man in charge knew every part and could adjust all parts to make a completed

unit to the new method of making parts from a carefully prepared drawing with sufficient information thereon so that when assembled the final unit will come together satisfactorily. It brings out, further, the present time method of manufacturing parts in large quantities at one time and having them available when needed.

The matter discussed in the paper of how to show dimensions on drawings should be determined by adopting whichever way produces the best result depending on the class of employees but the gage system marked in decimals should be used in figuring drawings.

OPERATION OF GRINDING WHEELS IN MACHINE GRINDING

BY GEORGE I. ALDEN, WORCESTER, MASS.

Member of the Society

Long experience in the use of grinding wheels has developed facts in regard to their action, which, however, have been stated only as empirical rules. Such rules are easily forgotten or confused by operators because they are not related in any obvious way to any known principles by which results may be predicted. For example, what is the effect upon a wheel of increasing the speed of work, or of increasing the diameter of the work, or of diminishing the diameter of the wheel?

This paper gives an analysis of the action of the wheel when in operation. It shows the distinction between the radial or real depth at which the wheel cuts and the depth which the abrasive grain in the wheel cuts into the material being ground. This latter depth is termed the "grain depth of cut," which is the *controlling factor* in securing the correct working of the wheel. This grain depth of cut is indicated in Fig. 1, where

C = the center of the wheel

c = the center of the work

OP = the radial depth of cut

OQ = the arc of contact of wheel and work.

Owing to the revolution of the wheel and work, a cutting point O on the wheel will move to P in a certain time and a point Q on the work will move toward P to some point as W . The chip removed is represented by OQW and the *grain depth of cut* is WS .

When a grinding wheel is working properly, the abrasive grain of the wheel may be considered as cutting small chips from the work, and the surface of the work as cutting or wearing away the bond of the wheel. It is quite evident that the greater the grain depth of cut, the more effective will be the action of the work upon the bond of the wheel. So long as the bond is being worn away just as fast as the abrasive grains of the wheel are being worn down, the

wheel will continue to work well. If the bond is cut away too rapidly, the wheel will appear too soft, and will wear away too rapidly. If the cutting grains wear down faster than the bond is cut or worn away, the face of the wheel will become glossy, and the wheel will not cut freely. These considerations lead directly to the conclusion that the action of a given wheel on a given kind of work is almost entirely dependent upon the grain depth of cut. If the grain depth is too great, the wheel wears away too rapidly. If the grain depth is too small, the wheel may glaze.

FIG. 1

It is therefore important to know how the grain depth of cut may be regulated.

As is evident from Fig. 1, one relation that affects the grain depth of cut is the ratio of the work speed to wheel speed, represented by QW and OQ . It is also affected by changes in diameter of wheel or work. Assuming

- a Other factors remaining constant, increase of work speed increases grain depth of cut, and makes a wheel appear softer
- b Similarly, a decrease of wheel speed increases grain depth of cut
- c Similarly, diminishing the diameter of the grinding wheel increases grain depth of cut, and increasing the diameter of the wheel decreases grain depth of cut
- d Similarly, making the diameter of work smaller increases grain depth of cut. Conversely, making the diameter of work larger makes grain depth of cut smaller

In applying the principle that grain depth of cut is the main factor, the correct relative speeds of work

and of wheel must be found by trial for each wheel and each kind of work. When this has been done, the principle of grain depth of cut will enable one to know the direction in which to make the changes of work speed or wheel speed, to adapt the wheel to changes in its own diameter, or to other sizes of the same kind of work.

In the foregoing it is assumed that the object of grinding is to remove stock rapidly. Often, however, the character or finish of a ground surface is of primary importance. From the point of view of grain depth of cut, a smooth surface by grinding would be obtained if the grain depth of cut were very small, and therefore the work speed should be relatively slower for finishing than for roughing. That the bond may be worn away by a very small grain depth of cut, a softer wheel would be used for fine finishing than for roughing. A very hard glazed wheel may sometimes produce a mirror-like surface on the work; the action in this case being a sort of burnishing process.

The following formula expresses the grain depth of cut:

$$d = \frac{r}{Vn} \sin(A + B)$$

where

r = surface velocity of work

V = surface velocity of wheel

n = number of cutting particles per unit length of circumference of wheel.

In the paper a table is given of arcs of contact for different diameters of wheel and work, and examples are worked out to show the change in grain depth of cut due to changes in radial depth. These show that increase of radial depth does not increase grain depth in the same proportion. In one case, doubling the radial depth increased grain depth only 40 per cent. If, however, $\sin(A + B)$ is increased, say 40 per cent by doubling the radial depth, the formula shows that r/V might be diminished by about 30 per cent without changing the grain depth; but these changes, which have not varied the theoretical value of grain depth d have increased the rate of production 40 per cent. This indicates that production may be increased without increasing grain depth of cut, by increasing the radial depth of cut, and at the same time diminishing the work speed a less per cent than the radial depth is increased. In practice this method of increasing production requires rigidity of machine and work.

DISCUSSION

C. H. NORTON said that he wondered whether those interested had got the thought which the author offered. It has to do in the operation of grinding machines with the selection of the speed of the work for a given radial depth of cut. The paper indicates that the production may be increased by slowing the working speed and increasing the radial depth, without destroying the wheel as rapidly as if it were

attempted to cut to a greater depth or with a rapid revolution of the wheel.

THE AUTHOR, in answer to an inquiry by M. D. Hersey as to the effect of pressure of the wheel against the work, said, that for a given radial depth of cut, the pressure depends on the condition of the wheel. If the wheel cuts badly the pressure is heavy and vice versa. The faster the work is worn down the faster it wears away the bond, the friction between the work and wheel is large and pressure becomes greater.

In response to further inquiry as to the importance of the rigidity of support of the grinding wheel and its rigidity in the bearings, it was brought out that the life of the wheel and the amount of effective work and the rapidity with which it produced are dependent upon rigidity. Mr. Norton said that he used very carefully made bearings and that they were fitted to a degree of nicety where the ordinary engineer would condemn them because they ran hot. A thin lubricant is used and good results are secured.

FRICTION LOSSES IN THE UNIVERSAL JOINT

BY P. F. WALKER, LAWRENCE, KANS.

Member of the Society

AND W. J. MALCOLMSON, LAWRENCE, KANS.

Non-Member

During the past three years two standard makes of universal joints have been under observation and test in the laboratory of the Mechanical Engineering Department of the University of Kansas, with the object of determining the loss of power due to friction in the joint while operating under such loads and speeds as are common in automobile service. In each case two complete joints connected by an intermediate shaft were employed, so that in service during the tests power was transmitted through the set from the primary shaft to a parallel secondary shaft, Fig. 1. All observed data relate therefore to the loss occurring in two joints. The main dimensions were as follows:

	Joint No. 1	Joint No. 2
Diameter intermediate shaft.....	11½ in.	13½ in.
Length of shaft.....	22 in.	13 in.
Dimensions of each bearing.....	3¼ x 3¼ in.	1½ x 1½ in.
Maximum angle of deflection....	15 deg.	14 deg.
Horsepower rating.....	16 h.p.	30 h.p.
Lubricant used.....	hard grease in each	

The kinetic relationships embodied in the universal joint is such that the driving and driven shafts must be parallel in order to secure a uniform velocity ratio. If the second shaft makes an angle with the first, it will have a variable velocity, the extent of which will depend upon the size of the angle.

Further, in assembling the joints, the forks on the

intermediate shaft should be in the same plane. This point is not appreciated by the average person using universal joints, about half the joints being wrongly assembled with the forks on the intermediate shaft at 90 deg. or some other angle to each other. This gives rise to unsatisfactory operation and the joints of the machine are often indiscriminately condemned.

The actual determination of the friction losses in

FIG. 1 ARRANGEMENT OF MACHINES

universal joints, such as are used in automobile power transmission, under proper conditions of speed and load requires extreme delicacy and care. The difficulty in this problem lies in the fact that the amount

the input and the output. As these two quantities are comparatively large and nearly equal, any small error in their determination would produce a relatively

FIG. 3 JOINT NO. 1. FORKS AT 90 DEG., 800 R.P.M.

large error in the derived value of the loss. In the actual performance of any experimental work to determine this loss of power in the joints as friction, the problem becomes that of measuring accurately the power supplied to, and that received from the section of shafting which includes the joints.

In considering the several possible methods of meas-

FIG. 4 JOINT NO. 1. CONSTANT LOAD, 800 R.P.M.

FIG. 2 JOINT NO. 1. FORKS IN SAME PLANE, 800 R.P.M.

of power dissipated in the joint, as friction loss, is very small compared with the amount of power transmitted. Practically the only way to measure the loss in the joints is to determine the power delivered to one of the shafts and the power delivered by the other end. The losses would then be the difference between

using the power transmitted by line shafting the accuracy required to determine the relatively small value of the friction losses in the universal joints put the general class of dynamometers out of the question, and it was early decided that to obtain any accuracy whatever with the facilities and time available, electrical methods should be used throughout and it was decided to use the Puffer Modification of the Kapp Load-Back Method of Testing, as described in Foster's Electrical Engineer's Pocket Book (1908 ed.).

Briefly, in this method of testing two machines, preferably of the same size, make and rating, are both electrically and mechanically interconnected. One machine operates as a motor and drives the other mechanically as a generator. The current generated by the generator is loaded back on the motor supply line. Since one machine takes power as a motor and the other returns power as a generator, the net power

in the joints are zero for conditions of straight line drive, with all other conditions remaining the same, the friction losses for a certain displacement of the intermediate shaft would be found by subtracting from the total losses of the system at that displacement the total losses under conditions of straight-line drive.

With the forks at 90 deg., there was noticeable a distinct vibration and knocking which was not pres-

FIG. 5 FRICTION LOSS AT VARYING ANGLES, VALUES DERIVED FROM AVERAGES

taken from the line is only that which is required to supply the total losses of the system.

The actual procedure in carrying out the experiments consisted in first running the machines with all shafts in the same straight line and determining the total losses of the system as a whole. With the main shafts kept parallel, and keeping as nearly constant as possible all other conditions, such as speed, temperature, lubrication, and general conditions, the losses of the system were again determined for a certain angular displacement of the intermediate shaft. Readings were taken at different angular displacements and similar runs were then made for various speeds and loads. Experiments were made for both sets of joints both with the forks on the intermediate shaft at 90 deg. to each other and with the forks in the same plane. Assuming, correctly, that the losses

FIG. 6 JOINT No. 2. FRICTION LOSS AT VARYING ANGLES, VALUES DETERMINED FROM AVERAGES

ent when the joints were properly assembled. This vibration increased as the angle of deflection increased, sometimes becoming so pronounced for the larger angles that it was found to be unsafe to try to operate.

Two general methods for securing readings which should cover variations, both in load and angle of inclination were followed. One consisted in lining the shaft exactly for straight-line drive and under this condition of zero loss operating the joint through a wide range of loads. This being done, the driven machine would be offset to give any desired angle and the apparatus then be operated through exactly the same range of loads, speed being held constant for all conditions.

The other method consists in holding both speed and transmitted load constant during the entire se-

ries of observations. In this case, with the shafts in direct line for straight-line drive, the initial value of total loss corresponding to zero loss in the joint is determined. After this, with the machines still running, the generator would be moved to give the proper offset angle and the readings for that condition taken with but a few moments delay. This would be repeated for as many angles as desired.

Figs. 2, 3 and 4 show curves which represent the individual readings of total losses, and Figs. 5 and 6

All such differences, each representing a loss due to angularity, were then cast onto one common base line and a single representative curve established for each angle investigated. It did not seem necessary to extend the work to secure data for all conditions of load and speed for the joints improperly assembled with the joint forks set at 90 deg. on the intermediate shaft. Enough was done to demonstrate the necessity of assembling properly.

In the calculation of efficiency of the joints it seemed wise to make the conclusions applicable to a complete system including the two joints necessary to secure parallel operation of the main shafts. In case a knowledge of the efficiency of a single joint is desired, it may be assumed without sensible error that the loss is one-half of the amount here recorded and that the efficiency would be indicated for each condition by a fraction which is the arithmetical mean of the figure here given and unity. The difference between the amounts of power transmitted by the two joints is so small as to be outside any possible limits of observation.

The efficiency is calculated directly from the curves of derived values of friction loss. For any power and angle the friction loss in the two joints is read. The power is, in all cases, the amount transmitted at the joint, it being the sum of the load delivered by the driven generator and the losses of that machine. These latter losses have been based on separate tests made to determine the machine characteristics. It follows, therefore, that efficiency equals the power transmitted divided by that power plus the friction loss; that is, it is power delivered divided by power received by the joints.

Fig. 7 shows the efficiencies of the universal joint sets in the various conditions of operation. From these curves it is noted that for loads amounting to one-half the rating of the set, or more, the efficiency is nearly constant and the loss very small for angles of inclination not exceeding 6 deg. For larger angles the loss becomes an appreciable amount. The constancy in the efficiency fraction indicates a constant value of the coefficient of friction on the joint journals, since the bearing pressures are proportional to power transmitted while speed remains constant. Under conditions of service the questions of lubrication and protection from dust are important. In the efficiency calculation a downward tendency was noticeable at the largest loads although it is not visible on the curves. Doubtless it marks the point where the bearing pressures on these journals make lubrication imperfect. The rocking motion of the journals tends to squeeze out the oil.

FIG. 7. EFFICIENCY CURVES

are curves showing the true friction loss. Fig. 5 pertains to joint No. 1 as operated at the two speeds of 1000 and 800 r.p.m. Fig. 6 gives corresponding information for joint No. 2. They represent the final results of all of the work and are located by points which are fixed by taking averages of many observations. In changing from the basis of total losses to friction loss in the joints alone, the total loss for zero angle was first deducted from all other values of total loss, determined during that particular day's work.

RAILROAD SESSION

REPORT OF SUB-COMMITTEE ON RAILROADS AND CONTRIBUTED DISCUSSION

AT the Railroad Session of the Annual Meeting, Wednesday afternoon, December 2, a report was presented by the Sub-Committee on Railroads on Steam Locomotives of Today, which outlined the principal features of the locomotive problem as it now appears to railway mechanical officials. The subject was topically arranged, and each of the topics was discussed, some of the contributed discussions being exhaustive in character and of more than ordinary interest. The report of the Committee, which was brief, is reproduced in complete form below, while the discussions are presented in abstract form.

STEAM LOCOMOTIVES OF TODAY

Recent progress and improvement in the efficiency and capacity of steam locomotives has been of such remarkable character and extent that a record in the proceedings of this Society is justified.

Steam and electric locomotives as rivals in the same field has been a favorite subject for discussion before engineering societies, and it is easy to start arguments in favor of each of these rivals among the partisans interested. Whether or not the steam locomotive is to be displaced by the electric is, of course, an important question which will in time be settled by the court that settles all such questions, that of the treasurer's figures. For the present and for the immediate future the burden of transportation falls and will continue to fall upon the steam locomotive. If the steam locomotive is to be perpetuated it is fitting that it should be improved to the utmost limit. If it is to be finally displaced it is fitting that it shall be so improved in order that progress to something better shall be intelligently developed upon a solid foundation. This discussion will be confined to the steam locomotive, its progress in the recent past and its possibilities for the near future.

PROGRESS IN CAPACITY

While efforts individual in character and extent were made in this country before that time, the first consistent and systematic plan to secure the utmost power of locomotives within given restrictions of weight and cross-section clearance was inaugurated 20 years ago. This plan began with an eight-wheel or American type passenger locomotive, built for an eastern railroad in January 1895. This locomotive weighed 116,000 lb., with 74,500 lb. on driving wheels. It provided a tractive effort of 21,290 lb. While this locomotive was not the most powerful in passenger service at that time, it was the first of a chain of passenger locomotives leading in a connected series, by the same builders, up to and including recent designs of the Mountain type, representing the largest passenger type of present practice. This type has four-wheel leading trucks, eight driving wheels and two trailing wheels. The largest of the Mountain type weighs 331,500 lb.

with 240,000 lb. on driving wheels and produces a tractive effort of 58,000 lb., or about three times the tractive effort of the first design of the series built during a period of 20 years.

In the year 1898 the engineering and railroad world was interested by the appearance of the largest and most powerful locomotive built up to that time. This was of the Consolidation type with a two-wheel leading truck and eight driving wheels. This locomotive was built in Pittsburgh and for a number of years was the largest and most powerful of its type, and the largest and most powerful locomotive in the world. Its total weight is 230,000 lb., weight on drivers 208,000 lb. and tractive effort 53,300 lb.

Today the most powerful freight locomotive has two leading and two trailing wheels and 24 driving wheels. It gives a tractive effort of 160,000 lb. and weighs 410 tons. This locomotive has hauled a train of 251 freight cars weighing 17,912 tons, exclusive of the locomotive. The total length of the train was 1.6 miles, the maximum speed attained was 14 miles per hour. This required a maximum drawbar pull of 130,000 lb. This locomotive has six cylinders and three groups of driving wheels.

A freight locomotive has recently been built having two cylinders and a single group of driving wheels which develops a tractive effort of 84,500 lb. Such has been the progress in capacity.

This progress has been rapid, perhaps somewhat too rapid with respect to improvements in operating facilities and progress in other features of railroad equipment. It has been rendered possible by corresponding developments of factors making for greater efficiency in boilers and in engines. During the past 20 years in this country locomotive development in capacity and in efficiency, particularly during the past five years with respect to efficiency, has been remarkable and is worthy of record with progress in marine and stationary engineering.

In Europe the relatively high cost of fuel led to efforts to improve efficiency before this problem aroused serious attention in this country, but physical limitations more rigidly restricted the size and weight of

locomotives in Europe. Our problem is to secure maximum efficiency combined with great size, great weight and great power which is more difficult. Since the development in the size and weight has been tremendous, even though these limits may not yet have been reached, it is now appropriate to concentrate on efficiency.

For a number of years the physical capacity of the fireman to shovel horsepower through the fire door determined the capacity of the locomotive at speeds. Mechanical stokers have removed that limitation. It is now possible to fire six tons, and more, of coal per hour into a locomotive firebox. This has changed the problem into one of getting the maximum amount of heat out of the coal and using it economically in the cylinders. With the large figures now prevailing for drawbar pull and weight it is fitting that closest attention should be given to the best possible use of every pound of metal and every pound of coal. Due to recent application of several economy producing and capacity increasing factors great improvements have already been made with promise of more to come. Then the great work of building up the efficiency of the average locomotive to the standard of the best will follow in natural course.

Among these economy producing and capacity increasing factors are the following improvements:

- Boiler design in relationships of the factors making up heating surface
- Firebox design
- Front end design, draft appliances, exhaust nozzles
- Ashpan design as to air openings
- Superheating
- Compounding
- Feedwater heating
- Firebrick arches and circulating supporting tubes
- Valve gear
- Detail design to secure reduced weight of reciprocating parts and other parts
- Use of high-grade alloy steels to reduce weights
- Mechanical stokers
- Labor-saving devices for the engineman and fireman
- Improved counterbalancing to permit of greater weight on driving wheels by reducing dynamic stresses

And yet to come is powdered fuel with possibilities unknown in scope and in importance. Powdered fuel is in reserve, promising the ideal method of complete combustion under control more perfect than is possible with present methods other than oil burning and perhaps with economies impossible to obtain with oil.

PROGRESS IN EFFICIENCY

Valuable comparisons may be drawn from the best results of ten years ago and of today. At the Louisiana Purchase Exposition in 1904 the tests made by the Pennsylvania Railroad revealed important figures

concerning locomotive performance at that time. It was shown to be possible to obtain equivalent evaporation from and at 212 deg. of 16.4 lb. of water per sq. ft. of heating surface, indicating the power of locomotive boilers when forced. It was shown that when the power was low, the evaporation per pound of coal was between 10 and 12 lb., whereas the evaporation declined to approximately two-thirds of these values when the boiler was forced. These results compared favorably with those obtained in good stationary practice, whereas the rate of evaporation in stationary practice lies usually from 4 to 7 lb. of water per ft. of heating surface per hour. In steam consumption the St. Louis tests showed a minimum of 16.6 lb. of steam per i.h.p. per hr. In coal economy the lowest figure was 2.01 lb. of coal per i.h.p., the minimum figure for coal per dynamometer h.p. was 2.14 lb. These records were made after the superheater had become a factor in locomotive practice and they represent economies attained by aid of the superheater in one of its early applications. This is important in the light of the recent development of the superheater. These remarkable figures have never received the attention which they deserve from engineers. They serve, however, to show that 10 years ago a steam locomotive had attained results which were worthy of the best attention of the engineers of the time. Since then greater progress has been made and today locomotives of larger capacity than those concerned in the St. Louis tests have given better results.

Voluminous records of recent investigations of locomotive performance taken from the Pennsylvania Railroad test plant at Altoona show that the best record of dry fuel per i.h.p.-hr. down to the present date is 1.8 lb. with a large number of less than 2 lb., while the best performance in dry steam per i.h.p.-hr. is 14.6 lb. with a large number less than 16 lb. A reduction of 10 per cent in fuel and 12 per cent in water is remarkable as a result of a development of 10 years. This coal performance was recorded by a Class E6S Pennsylvania Railroad locomotive while running at 320 r.p.m. and developing 1245.1 i.h.p. The same locomotive gave a fuel rate of 1.9 lb. while running at the same speed and developing 1750.9 i.h.p. The best water rate was given by Class K2Sa Pennsylvania Railroad locomotive while running at 320 r.p.m. and developing 2033.1 i.h.p. These high powers indicate that the locomotives were not coddled as to output of power in order to show high efficiencies, but that high efficiencies accompany actual conditions of operation in severe service. As to power capacity expressed in terms of evaporation, it is interesting to note that the maximum equivalent evaporation from and at 212 deg. per sq. ft. of heating surface per hour on the Altoona test plant is 23.3 lb. These figures of high efficiency were obtained from locomotives which represented not only very careful, general and detail design, but their design included several of the improvements making

for greater capacity and higher efficiency, without which the results could not have been attained.

Having in mind the facts that steam locomotives are power plants on wheels, built to meet rigid limitations of weight, both static and dynamic, and that the use of condensers is impossible, engineers in general must admit the high character of the work of locomotive designers which has attained these results.

Greater efficiency which is revealed on the test plant and through reports of engineers would be important because it proves that progress is being made in the possibilities of locomotive performance. Improvement which is revealed by operating statistics and which, therefore, appears in the records of the treasurer's office is the real test in this case. It is important to know that increased power of locomotives attained largely through the development of economy producing and capacity increasing factors has produced results which the financial reports of railroads prove beyond question. A recently published list of train tonnage on 45 prominent railroads indicates that 16 of these roads have increased their average freight train loads by over 30 per cent during the last five years. Credit must be given to the improvement in the locomotive for most of this development. These figures re-

veal the value of increased power and efficiency of steam locomotives and the end is not yet in sight.

WHAT REMAINS TO BE DONE

American locomotive development to its present state would have been impossible without the use of the improvements already mentioned. It is believed that all these are capable of still further development, making for still greater economy in the use of fuel and, therefore, promising greater power capacity. It is the object of your Committee to present these possibilities for discussion by those who are engaged in perfecting and improving steam locomotive practice in this country. It is the hope of your Committee that engineers who are devoting their attention to the design of locomotives as a whole and those who are engaged in the development of the various details which have contributed to the high efficiency of the steam locomotive of today will discuss the progress of the recent past and reveal possibilities for future development and improvement in capacity and efficiency.

E. H. CLARK		} <i>Railroad Committee</i>
W. F. KIESEL, JR.		

ABSTRACT OF DISCUSSION

F. F. GAINES contributed a written discussion in which he stated that boiler and firebox proportions must be carefully studied and chosen so as to produce capacity as well as efficiency. These proportions are now being worked out on a scientific basis. Modern large engines have a ratio of tube heating surface to total heating surface as high as 20. On small engines with deep fireboxes this ratio formerly ran as low as 8. A desirable figure for this ratio is 12. This can be obtained by the use of a combustion chamber which lengthens the firebox and shortens the flues. Where large grate areas are required, as in the large Erie Triplex, it is almost impossible to provide a wheel arrangement that would not necessitate the firebox extending over the drivers. With the use of a combustion chamber this can easily be accomplished, as the mud ring may be as high or higher than the bottom waist line of the boiler. The ratio of total heating surface to grate area should not be over 80, and more economical results are obtained if it is 65.

With ample grate area and firebox heating surface the desired results cannot be obtained unless the affiliated parts are correctly designed. The grates should be of such mesh as the grade of fuel requires; the mesh being as large as possible without the fuel dropping through. The grates should also have the maximum of possible air openings as well as air openings in the side bearers. The opening on the top should be a minimum and expand as it goes down, so that any ash, slate or clinker that can pass through the top will easily pass through and not clog the grates. Ashpan openings are generally restricted and do not admit sufficient air for economical or maximum combustion. The proper arrangement of front ends is very essential to the uniform drafting of the fire; the lower the exhaust pipe,

the less the back pressure and consequently the greater the mean effective pressure.

In this country feedwater heating is confined to a limited number of cases and cannot be said to be recognized generally as a factor in fuel economy. Experiments made on several engines by the writer showed about 10 per cent economy, which was considerably offset by difficulties in maintenance. Eventually, however, we will develop a type of feedwater heater that will eliminate the objections. It would appear that the most feasible plan would be a type of open feedwater heater, which would be located between the frames of the engine and underneath the boiler, using the exhaust from the air pumps, boiler feed pumps, and part of the main exhaust. In doing this it is thought that ultimately instead of using the present form of exhaust draft to effect combustion, with its consequent back pressure due to restriction of nozzle, a form of forced draft of the blower type will be used. Under these circumstances the exhaust openings from the cylinder to the atmosphere can be made without any restriction whatever, thereby greatly eliminating back pressure. The steam required for operating the auxiliary and forced draft would use but a small proportion of the horsepower gained. Previous experiments would also indicate that a type of centrifugal pump would be much more effective and positive for boiler feeding than one of the reciprocating type.

American railroad practice is averse to adding anything to the locomotive in the way of additional apparatus which complicates its operation or adds to its complexity. The demand for the utmost economy will eventually bring about a satisfactory method of feedwater heating so that in connection with superheating, liberal firebox heating surface,

and possibly compounding, we can obtain the maximum possible economy from the fuel used.

F. J. COLE called attention in a written discussion to the fact that in recent years, locomotives have increased so much in power that methods formerly employed are no longer adequate in proportioning the grate, heating surface, length and diameter of tubes, etc., when the class, tractive power and limitations of weight are known.

The size of cylinders is usually fixed by the permissible axle load allowed upon the track or bridges, in connection with the type, driving wheel diameter, boiler pressure and factor of adhesion. After these fundamental features are decided upon, the boiler proportions must be outlined to see whether the required amount of heating surface can be obtained without exceeding the limits of weight.

There are two general questions involved in the consideration of this subject, namely, how many pounds of steam per hour are required to supply the cylinders in order to develop the maximum horsepower; and what proportion of grate, firebox and tube heating surface will best produce this amount of steam.

The locomotive, unlike most steam plants, varies in the speed and power developed. It must be able to run at any intermediate speed between starting and its full velocity and at the same time develop all degrees of tractive power within its capacity. At slow speeds the maximum pull must be exerted in order to start the trains easily, and for this reason the live steam is admitted to the cylinder during 80 to 87 per cent of the stroke. As the speed increases it is necessary to reduce the admission period, thereby increasing the expansion of the steam. Therefore for any speed there is some point for the valves to cut off the live steam, at which the engine will develop its maximum power. There is also some minimum velocity at which the full horsepower of the locomotive is attained; after this velocity is reached the horsepower remains constant or slowly decreases. This critical point may be taken at 700 to 1000 ft. per minute piston speed.

It has been customary to use certain ratios, based on cylinder volume, for locomotive proportions. These ratios left to individual preference such matters as rate of combustion per square foot of grate, length of flues, evaporative value of firebox heating surface or value of tube or flue heating surface in relation to the length, making it desirable to proportion boilers upon more uniform methods in which these variable factors are given due consideration.

The writer collected a considerable amount of data on this subject and drew up a report with the object of reducing this matter to a more uniform basis, substituting for the ratios hitherto employed, cylinder horsepower requirements. Suitable values were assigned to grate surface, tube heating surface, etc., with corresponding evaporative values, so that the balance between the amount of steam required by the cylinders and the amount of steam which the boiler was capable of generating could be expressed in percentage of cylinder horsepower. The tests made on sectional boilers on the Northern Railway and the Paris, Lyons & Mediterranean Railway of France, those of Dr. Goss on a Jacobs-Shumert boiler, and tests by the Pennsylvania Railroad on the Altoona testing plant were examined in order to obtain data on which to base the evaporative values of different points of the boiler. It is obvious that the evaporative

value of a boiler tube of given diameter varies greatly with its length. The temperature of the firebox is fairly constant under similar conditions of draft and rate of combustion, therefore the temperature of the smokebox will be reduced with an increase in the tube length. While some additional draft will be required to draw the gases through the tube, yet the net result is a greater temperature absorption between the firebox and smokebox. The thermal efficiency of the engine is increased within certain limitations by the use of long flues. The economical length of tube is determined mostly by the number and arrangement of wheels of the engine required and only partly by thermal conditions.

About 1899 the wide firebox Atlantic (4-4-2) type was introduced. Because the firebox was placed behind the driving wheels, the grate surface could be made to suit the power of the locomotive. It was, therefore, no longer necessary to force the rate of combustion as heretofore to 180 and 200 lb. per sq. ft. per hour. Very uneconomical results had been obtained when high rates of combustion were necessary, as much unburned coal was drawn through the tubes into the smokebox and thrown out through the stack by the violent draft. With the Atlantic, tubes of 15 and 16 ft. and sometimes longer were necessary. While at first some apprehension from leakage was felt with tubes of this length, it was soon found that there was no more difficulty in maintaining long tubes in good condition than short tubes. With the introduction of the Pacific (4-6-2) type, the Mikado (2-8-2) type and other locomotives having trailing trucks, still longer tubes were required. Tests made on long tube boilers, compared with older locomotives having shorter tubes, showed a noticeable reduction in smokebox temperatures.

Instead of the old arbitrary and unsatisfactory method of designing heating surface by cylinder ratios, the idea of using the cylinder horsepower suggested itself as forming a very desirable basis. Curves were prepared from the most recent available data showing speed factors or drop in m. e. p. in relation to velocity. With saturated steam the average maximum horsepower is reached at about 700 ft. piston speed per minute, speed factor 0.412; constant horsepower is obtained at 700 to 1000 ft. piston speed, and then slightly decreasing at higher velocities for average conditions when engines are especially constructed for the highest speeds. For superheated steam the average maximum horsepower is reached at 1000 ft. piston speed, speed factor 0.445 and constant horsepower at higher speeds. Because the horsepower is based on piston speed, the stroke and diameter of wheels are omitted in the following figures, the calculation for saturated steam becoming by cancellation:

$$\frac{0.85 P \times 0.412 \times 1000 \times 2.4}{33,000} = 0.0212 \times P \times A$$

in which

A = area of one cylinder in sq. in.

P = boiler pressure

0.412 = speed factor

In a similar manner the horsepower calculation for superheated steam becomes

$$\text{h.p.} = 0.0229 \times P \times A$$

using 0.445 as the speed factor.

The maximum horsepower can sometimes be increased when the locomotive is operated under the most favorable conditions. It is considered safer to take figures which

represent average conditions rather than the unusual figures obtained when all conditions are most favorable.

The horsepower basis affords many additional advantages in designing locomotives. For instance, in determining the maximum amount of water and coal required per hour, the size of the grate is found to be proportional to the amount of coal that can be burned to the best advantage, to be varied according to the quality. Knowing the amount of coal required per hour directs attention to the question of hand firing or the use of a mechanical stoker. Knowing the amount of water evaporated per hour determines the location of water stations, size of tender and tank, and also forms the basis for other features of the boiler, such as stack, size of injectors, safety valve capacity, and the size of steam pipes.

From the reports of Pennsylvania Railroad testing plant at St. Louis and Altoona, and from road tests, the conclusion is reached that a horsepower can be obtained from 25 to 29 lb. of saturated steam in simple cylinders with piston speeds of 700 to 1000 ft. per minute. A fair average value has been taken as 27 lb., and in a corresponding way 23½ lb. for compound engines, 20.8 lb. for steam superheated 200 deg. and over, and 19.7 lb. for superheated steam used in compound cylinders. These figures provide steam for auxiliaries. While careful tests show that the evaporation can be increased under the most advantageous conditions, it is considered better practice to take the lower figure in order to provide a margin for average conditions.

Pyrometer tests recently made by the Pennsylvania Railroad at Altoona with various locomotives on the testing plant showed the temperature curves of tubes of various lengths and diameter. From these curves the increase or decrease of tube evaporation may be calculated. Short tubes have much greater evaporative value per square foot of heating surface than long tubes, but they discharge the gases into the smokebox at much higher temperatures. Therefore, while the heat absorbed per foot of length is much greater for short than long tubes, it is not so economical, and the short tube boiler, other things being equal, requires more coal for a given evaporation. Where tube lengths of 12 or 14 ft. were common 14 or 15 years ago, lengths of 20, 22 and even 24 ft. are used in the modern locomotive. The result is that the smokebox temperatures have decreased from 750 to 800 deg., to 550 to 600 deg., the only increase of energy required being the slightly greater draft in the smokebox to pull the gases through the long tubes. This is not intended as a defense of the long tubes in modern engines, especially of the 4-6-2, 4-8-2, Mallet and other types, because in most cases their construction requires long boilers. Nevertheless tests show that economy results from the better utilization of heat in the modern engine than in older types because the range of temperature between the furnace and the stack is greater with the long tube locomotive.

As a result of these investigations, conclusions have been arrived at as follows:

Firebox evaporation. An evaporation of 55 lb. per sq. ft. of firebox heating surface, combustion chamber and arch tubes has been adopted. The greater absorption of heat by the firebox than by the rear portion of tubes per unit of area is largely due to radiant heat. This varies as the square of the distance from the surface of the fire to the

sheets separating the gases from the water. Again it is probable that within certain limitations, the amount of heat absorbed is independent of the heating surface and is a function of the grate area or the area of the bed of live coals. Assuming that there is sufficient heating surface to absorb the radiant heat, it is probable that very little additional heat will be absorbed by increasing the firebox heating surface. It therefore follows that the relatively greater area of the fire in proportion to the absorbing surface in wide firebox locomotives is more efficient than in the old narrow firebox.

Diameter, Length and Spacing of Tubes and Flues. The evaporative value in pounds of water per square foot of outside heating surface has been approximately calculated for 2-in. and 2¼-in. tubes, and for superheater flues of 5⅜ in. and 5½ in. The range of length is 10 to 25 ft. and the spacing ⅜ in. to 1 in. The best available data show that the evaporative value of a tube or flue varies considerably with differences in length, diameter and spacing. Curves of temperature compared with length have been used as a basis for determining the evaporation for different lengths of tubes and flues. The rate of evaporation on this basis will vary directly as the difference of temperature of the tube or flue gases and that of the steam contained in the boiler.

Tubes and flues from 10 to 24 ft. long, spaced ⅜ in. to 1 in., outside diameter 2 in., 2¼ in. and 5½ in., will evaporate from 7.50 to 14 lb. per sq. ft. per hour.

Grate Area. Grate area required for bituminous coal is based on the assumption that 120 lb. of coal per sq. ft. of grate per hour is a maximum figure for economical evaporation. While 200 and 225 lb. have at times been burnt in small, deep fireboxes and the engines made to produce sufficient steam, it is wasteful of fuel and it has been found after numerous and careful tests, that the evaporation per pound of coal under these conditions is very low. If the rate of combustion is too slow, economical results will not be produced owing to the fact that at least 20 per cent of the coal burned produces no useful work in hauling trains, but is consumed in firing up, waiting at roundhouses or terminals, on side tracks, or to the fact that the greater portion of the time locomotives are used at considerably less than their maximum power.

For hard coal the grates should be proportioned for a range of from 55 to 70 lb. of coal per sq. ft. per hour, according to the grade of the fuel.

Complete tables of horsepower for saturated and superheated steam, evaporation of tubes and flues of various length, diameters and spacing, and diagrams of temperature of flue lengths have all been prepared to facilitate the calculations in determining the proportions of grate, firebox, tube and flue heating surface.

It must be remembered, however, that the boiler capacity for a locomotive, when other things are in proportion, cannot usually be made too large within the permissible limits of weight, and it can be shown by numerous tests that such increase in boiler capacity makes for considerable economy in the use of fuel and steam. For passenger service the boilers may often be made with advantage over 100 per cent.

In a general way, a boiler will have ample steam making capacity if proportioned by this method for 100 per cent.

provided the grate is sufficiently large and deep so that the rate of combustion at maximum horsepower does not exceed 120 lb. per sq. ft. of grate per hour for bituminous coal of average quality. For gas coal a smaller grate may be used, but it is better practice to use the larger grate and brick off a portion at the front end in order to obtain sufficient volume of firebox for proper combustion, because nearly all large modern engines are deficient in firebox volume.

C. D. YOUNG in discussing Mr. Cole's remarks, pointed out that some few years ago when large boilers were designed, the tendency was to make the ratio of the firebox heating surface to the total heating surface less than 6. This practice resulted in locomotives which, while efficient in evaporation, were not free steaming, as they lacked capacity unless very heavily drafted. Firebox heating surface should be at least 7 per cent of the total heating surface of the boiler. When this ratio is attained, good results will follow provided the tube heating surface has been properly proportioned. It should be realized that firebox heating surface is of comparatively greater effectiveness at mean and low rates of working than the remaining surface of the boiler. When working at high rates of evaporation, the tube surface is fully as effective as firebox surface, and for large capacity a large tube heating surface is necessary.

Beyond a certain length of tube there is too great a sacrifice of boiler capacity in the interest in economy in coal. The long tube presents a very serious resistance to the flow of the gases, and beyond a length—which appears to be about 100 internal diameters—this resistance increases without a corresponding increase in evaporation. The locomotive with a long tube is a slow steamer and a higher draft must be furnished in order to create an active fire. This rule—length of tube to be 100 times the internal diameter—has been applied to three new classes of Pennsylvania locomotives with exceedingly gratifying results; and confirms the earlier experiments made by the Pennsylvania Railroad upon this subject, as well as those made by M. A. Henry of the Paris, Lyons & Mediterranean Railroad of France.

J. T. ANTHONY in his written discussion remarked that from a furnace point of view, the principal points to be considered are grate area, flamework or volume, firing clearance and air supply. From the boiler point of view we must consider the extent and location of the heating surface.

In order to secure high efficiency, the grate area should be sufficient to keep the maximum rate of combustion below 100 lb. per sq. ft. per hour at full boiler capacity, as the losses due to imperfect combustion,inder discharge, front end gases, radiation and unaccounted for losses increase rapidly above this rate with a corresponding decrease in boiler efficiency.

The high efficiency at lower rates of combustion is due not only to a reduction in the heat losses enumerated above, but also to the relatively large proportion of the total evaporation that takes place around the firebox. Most of the heat received by the firebox heating surface is radiated directly from the fuel bed and luminous flames, only a small amount being due to convection or direct contact. The amount of heat received by radiation depends on the area of

the radiating surface and the difference in temperature between the radiating and cooling surfaces.

Flues receive their heat by convection, and the amount of heat so received, other things being equal, depends on the weight of the gases going through them. This varies with the rate of combustion, and as this rate increases the flue evaporation increases. Under the same conditions the firebox evaporation increases somewhat, due to the slightly higher temperature and increase in mass of flames, but not nearly as fast as the flue evaporation.

High firebox evaporation means high boiler efficiency, for the high heat absorption by the firebox reduces the temperature of the gases entering the flues; and for any one boiler, the temperatures of the gases entering and leaving the flues are directly proportional when reckoned above steam temperature. Hence a lower temperature of entering gases means lower front end temperatures and an increase in efficiency.

A large percentage of the bituminous coal burns above the grate as gas. The rapidity and completeness of the combustion of these gases depend on the amount of oxygen present and the thoroughness of the mixing. In a firebox with 60 sq. ft. of grate, with a rate of combustion of 60 lb. of coal per sq. ft. of grate per hour, an air supply of 20 lb. per lb. of coal and an average firebox temperature of 2000 deg., the volume of the gases evolved is about 1200 cu. ft. per second. A firebox of this size would have a cubic capacity of about 200 ft., and would have to discharge and be refilled with gases about 6 times per second. The average time available for combustion of each particle of gas would be insufficient for complete and proper mixing by diffusion. With the short time allowed, it is necessary to mix the gases by mechanical means, and this is generally accomplished by an arch or baffle which forces the gases through a restricted area, this area being not less than the net flue area.

Mere firebox volume is not sufficient of itself. It is necessary to have a flamework of such cross-section and length as to mix the gases intimately and provide sufficient space for burning before gases reach flues. In an ordinary firebox, without baffle or combustion chamber, the average length of flamework is only 5 or 6 ft. By the introduction of baffles and combustion chambers, this length can be increased from 10 to 15 ft., which results in not only more complete combustion but also in increased radiating surface, with a corresponding increase in firebox evaporation and a lowering in temperature of the escaping gases.

High efficiency is obtained at low rates of combustion in spite of the large air excess. The firebox absorbs a larger percentage of the heat evolved, and the amount so received depends primarily on the temperature of the fuel bed. It is possible that this temperature is higher with large air excess.

Firebox evaporation depends primarily upon the extent and temperature of the radiating surfaces and not on the extent of the heating surface. Increasing the firebox heating surface without increasing the grate area or flamework will result in very little increase in evaporation. An evaporation of 60 lb. of water per sq. ft. of firebox heating surface requires a difference of less than 100 deg. between the water and the fire side of the sheet. If sufficiently high firebox temperatures or radiating surfaces could be

obtained, it would be possible to increase this high rate of evaporation without forcing the heating surface to its capacity.

In the Coatesville tests, the two fireboxes gave an evaporation as high as 58 lb. of water per sq. ft. of heating surface. There was practically no difference in the total evaporation by each of the fireboxes when working at the same rate of combustion and with the same grate area. One of the fireboxes had 12 per cent more heating surface than the other.

Unless the fuel is materially changed, we are not likely in the near future to see any radical departures from the present type of firebox. Any improvement in the firebox efficiency will be obtained by paying particular attention to and making ample provision for grate area, firing clearance, gas mixing, flamework or combustion chamber space, and air supply.

H. B. MacFarland offered a written discussion in which he called attention to the amount of experimental work that has been done to determine the most efficient arrangement of drafting appliances, and yet it has been often and thoroughly demonstrated that the best arrangement for a front end for any given locomotive can only be determined after careful tests in service.

Pioneer work in this country in establishing scientifically the fundamental principles of front end action was done in the locomotive testing laboratory of Purdue University. The rapid development of powerful locomotives in the past few years calls for such an increase in the boiler capacity that it was questioned whether these recommendations were still applicable to the newer types of power. In order to demonstrate the best type of drafting, the Pennsylvania Railroad recently made a series of front end tests. Definite results and recommendations were obtained only after a very well worked out series of tests with a large number of different front end arrangements. From results obtained, however, they were not able to establish recommendations governing a proper design of front end appliances which may be generally applied to all classes of locomotives, so that such an arrangement has to be left to individual tests for each class.

That the present practice of locomotive drafting is accomplished at the expense of back pressure acting against pistons has been generally understood for a long time. Although generally understood that back pressure exists in all locomotives, the magnitude of the power loss due to this back pressure has not been generally recognized.

Since draft is a function of the front end arrangement in general and of the exhaust tip in particular, it naturally follows that the operation of the high powered locomotive boilers of the present day is at the expense of a very pronounced back pressure due to restricted tip. This is particularly true when the locomotives are operated at such rates of power as to force boilers to their maximum. Data were collected from tests conducted upon 18 different locomotives representing as many different types and working under such varied conditions as are encountered upon the Sante Fé System. These data show that for every 100 h.p. used as actual tractive power, there are 66 h.p. wasted through the exhaust, over 70 per cent of which may be credited to the excessive back pressure necessary to produce draft for the locomotive boiler.

The total capacity of a locomotive boiler has been greatly

increased during the past 10 years by the development of auxiliary apparatus such as superheater, brick arch, feed-water heater, stoker and other labor saving devices. An increase in boiler capacity has also been accomplished indirectly by improving the efficiency of the locomotive through improvements made in the valve gear, cylinder design, properly designed steam passages, etc. With all the developments and improvements, however, the fact remains that the determining factor in increased boiler capacity is, under the present arrangement, increased draft, and it follows that the most efficient method of producing this draft should be given serious consideration.

During complete tests made in the summer of 1914 of four different Prairie type locomotives, experiments were made to determine the effect of changes in front end arrangement. In each instance a number of runs were first made with the front end, as far as possible, in accordance with recommendations of the American Railway Master Mechanics' Association. Changes were then made in the front end arrangement to make each locomotive conform generally to the latest recommendations of the Pennsylvania Railroad. Assuming an efficiency of 100 per cent for the original arrangement, the tests show that a draft of 6 in. in the front end was produced with the new arrangement at a saving of 34.5 per cent in back pressure produced in the cylinders.

These tests show what may be accomplished by changes in front end arrangement, but when it is considered that the efficiency of the front end is very low from a thermodynamic standpoint, these gains in efficiency have very little effect on the total efficiency of the locomotive.

The power performance curves for one of the locomotives tested show that its maximum power was reached at a speed of 35 miles per hour; the locomotive developing 1350 i.h.p. and having 190 back-pressure h.p. There was a gain of 35 per cent in front end efficiency with the new front end arrangement. This means that the same draft was produced with a reduction of 35 per cent in back pressure, or at a saving of 66 h.p. This results in an increase of but 5 per cent in the capacity of the locomotive.

Curves taken from tests on a 2-8-8-2 Mallet show that maximum power was developed at a speed of approximately 17 miles per hour and that drawbar horsepower and back-pressure horsepower equalized at a speed of approximately 25 miles per hour. At this speed the locomotive exerted 950 drawbar h.p. and an equal amount was required to draft the boiler.

These tests have forcibly demonstrated the inefficiency of the present arrangement when viewed from a thermodynamic standpoint. The chief advantage of the present arrangement is mechanical efficiency; that is, it is free from any complicated parts and requires only minor adjustments. It is this feature alone that has enabled the present front end to exist to the present day.

In view of existing conditions, attention was attracted to the possibility of drafting by some method of forced or induced draft. Because of the impracticability of installing a system of forced draft, this form was abandoned. Induced draft has been successfully applied in stationary and marine service. The development of the steam turbine and progress in theory and construction of centrifugal fans make it seem logical that if the system could be so success-

fully applied to other fields it would find ready application to the locomotive. When the problem was presented to the manufacturers, they were able to calculate the size of the fan and the horsepower necessary to drive it to burn the required amount of coal. But when the space that such an apparatus would occupy was taken into consideration, they were unable to furnish either data or apparatus to meet the requirements satisfactorily. For this reason it was absolutely necessary to start in at the beginning and to develop such an apparatus.

After many experiments the MacFarland fan draft was developed. The diaphragm, nozzle pot, netting and other draft appliances were removed, leaving the front end clear for the reception of the turbo-fan unit. The smokebox proper was divided into two compartments by means of a sheet iron, air-tight partition, which made connection between the intake opening in the fan casing and the inner ring of the smokebox arch. The compartment next to the front tube was thus made separate and constituted the front end proper, the only opening being directly into the inlet of a high-speed direct-connected, centrifugal fan. The remaining compartment acted as a general housing for the fan and its operating power unit. Cylinder exhaust was led directly to the atmosphere by means of pipes leading from the front heads of the steam chest to a common stack located just ahead of the fan exhaust stack on top of the boiler. When the locomotive was working, the steam for the turbine was taken directly from the superheater; when the main throttle was closed the turbine was supplied through the blower line. While the fan used during this experiment was not mechanically correct or of sufficient capacity to develop the maximum power of the locomotive, it brought out many valuable points relative to the general performance to be expected from a system of this kind.

The experience gained led to the design of a larger fan unit which was applied to a New York Central switcher and a comparative test was made before and after installation. This installation was never satisfactory from a mechanical standpoint, because the unit employed was not adapted to the size of the smokebox on this particular locomotive. The tests further demonstrated, however, the possibilities of this form of draft for locomotives and justified the following conclusions:

- (a) That the engine could be successfully drafted with the MacFarland fan draft. A maximum of 9 in. of draft was developed in the front end with an average of 8¼ in. throughout one of the test runs, and the fan operated successfully against depths of fire ranging from 6 to 18 in.
- (b) That the exhaust could be muffled to any desired point by the introduction of proper netting stages.
- (c) That the engine could be operated practically smokeless.
- (d) That the engine burned a uniform and intense fire.
- (e) That full operating steam pressure was readily maintained.
- (f) That the back pressure on the engine was entirely eliminated.
- (g) That it was not necessary to use the exhaust steam for drafting the engine.

These tests have furnished data for the design of a special unit to overcome the mechanical difficulties which

have been brought out. The experience gained has also led to the development of an automatic control system to govern the speed of the turbine and consequently regulate the intensity of the draft.

C. E. CHAMBERS remarked that he had used long and short stacks, rectangular and oblique, single and double, but thought that the single type would give satisfaction if other things were right. The height of the exhaust pipe should be not more than one-quarter to one-third.

Front end diaphragm arrangement has a lot to do with an engine freeing itself. It must be kept 6 to 9 in. away from the sheet to give a clearance.

Many railroads have trouble from smokebox fronts overheating. This difficulty can be eliminated by placing the liner about 4 or 5 in. away from the door and filling with asbestos.

C. D. YOUNG gave statements based on facts developed by observation of locomotives on the testing plant at Altoona. These tests, during the last 10 years, embrace 23 passenger and 17 freight locomotives.

General use of the Schmidt type of superheater has had an influence in effecting a certain uniformity in the arrangement of the smokebox. The one-piece lift-pipe, connected directly to the outside of the stack, forms a very desirable and simple arrangement. Requiring only a short exhaust column, the advantage of a long stack may be obtained. A petticoat pipe, with its adjustable features, is not so desirable as the internal single-lift pipe. These adjustable features are a source of annoyance in that people not properly qualified are continually tampering with the arrangement, which results in an improper draft. It is most desirable that the gases have a free passage through the smokebox, and all possible restrictions between the tube sheet and stack should be carefully investigated as to their areas. Care should be taken to provide a passage through the superheater damper, which is at least equal to the area of the boiler and superheater tube outlets above the damper.

On railroads where there is practically little or no drifting, there would seem to be no requirement for a superheater damper. However, where a moderate amount of drifting is done, or where the locomotives are interchanged between divisions with few and moderate grades and divisions with heavy grades requiring a large amount of drifting, the automatic damper is a most essential feature for the protection of the superheater elements.

There has been a tendency of late to use exhaust nozzles having other than circular openings. The plain circular nozzle forms a steam jet which is too nearly cylindrical, or the shape of the stack, and the use of such a shape as the rectangular appear to break up the continuity or form of the jet and cause it to draw out a larger volume of gases. Both rectangular nozzles and nozzles of the dumb-bell shape have been used to success and with an increase in evaporation over that of the circular form. There has recently been developed on our testing plant a nozzle having four internal projections which appears to be more satisfactory than some of the irregular forms. With nozzles having other than a circular outlet, an increase in the evaporative capacity of the boiler of from 15 to 25 per cent has been obtained. In recent tests upon a large Pacific type, a nozzle with four internal projections has given a

maximum capacity in equivalent evaporation, from and at 212 deg., of 87,414 lb. per hour. This is an evaporation of 18 lb. of water per sq. ft. of heating surface per hour. With this capacity, an i.h.p. of 3184 was obtained. This same locomotive with a circular nozzle developed a maximum equivalent evaporation of 62,719 lb. of water per hour, resulting in an i.h.p. of 2501. No other change, other than in the exhaust tip, was made in the locomotive. The back pressure in both cases was practically identical.

Mr. Young also called attention to ashpan design as to air openings. He remarked that the air openings into the ashpan should be at least 15 per cent of the area of the grate. When the openings are of this size, the ashpan vacuum will be considerably less than one inch of water at the maximum evaporative rates.

This ratio has been found to be too large for the requirements of some switching engines. By installing ashpan dampers along the air inlets at the mud ring, this difficulty has been overcome. If the air inlets, in the ashpans of locomotives which stand around a large part of the time, are not reduced, it would be difficult for the fireman to prevent a large amount of steam from escaping from the safety valve.

H. B. OATLEY in presenting a written discussion on superheating stated that the locomotive boiler presented many limitations that have an important bearing on the design and construction of the superheater. The development of the locomotive, within certain fixed clearances, has been dependent upon the size of the boiler. As the boiler increased, wheels have been added to obtain proper weight distribution. Consequently, the boiler is no larger than is absolutely necessary and in the majority of cases it is insufficient in evaporating surface.

The application of a superheater to this boiler necessitates a reduction of about 15 or 20 per cent in the tube heating surface. Furthermore, a certain percentage of the gases, which formerly was available for evaporation of the water, must now be used for superheating the steam.

Taking this boiler with its deficiencies, the superheater has produced an economy of 25 per cent in fuel as a direct result of saving 33½ per cent of the total water evaporated per unit of power. As a result of this fuel economy, greater capacity of the locomotive has resulted.

If cylinder tractive power in per cent is plotted against piston speed, it will be seen that the average modern superheated steam locomotive, using between 200 and 250 deg. of superheat, has a greater available tractive power. This is due to the fact that a longer cut-off is possible with the superheater engine at comparative speeds. The limiting factor at the usual speeds is the ability of the boiler to furnish steam.

These results have been accomplished in the face of boiler limitations, parts of the locomotive being not adaptable to the use of highly superheated steam, and lack of experience in the organization which must handle the locomotive. The problems incident to these conditions are rapidly being worked out, and results shown by the superheated steam curve will soon be as basic as the saturated steam curve was a few years ago. The future holds a possibility for further saving by increasing the degree of superheat. For some time past large passenger locomotives have been operated very successfully with steam chest temperatures be-

tween 750 and 800 deg. This corresponds to 350 to 400 deg. of superheat.

The superheater engineer has only made use of the same variety of flue sizes as was used by the locomotive designer for tube sizes. If the superheater designer should be permitted the use of a size different from the two present standards, it would be possible to obtain in a superheater boiler, evaporating surface practically as great as in the saturated steam boiler. In this case the superheating surface would be a distinct net gain to the heat absorbing surface of the boiler. With a boiler and superheater thus arranged, greater capacity may reasonably be expected.

C. D. YOUNG remarked that it is now known that the economy due to superheating increases almost directly with the degree of superheat; and the usual type of fire-tube superheater produces its maximum superheat only when it is forced to the limit of boiler capacity.

This condition is not altogether desirable as the maximum economy should be obtained when the locomotive is working under moderate or average conditions and at an economical cut-off. A superheater that would give a uniform superheat under all conditions of working would apparently produce ideal results.

If our materials, in valves, cylinders and packing, as well as the lubrication, will withstand a certain high degree of superheat, there is no reason why we should not furnish this degree of superheat regardless of the boiler rate in order to effect the greatest economy in steam. With the usual Schmidt superheater we have observed steam temperatures as high as 670 deg., corresponding to a superheat of 291 deg. at a steam chest pressure which was 180 lb., while the boiler pressure was 206 lb. With these conditions the steam rate per horsepower hour was 19.3 lb., the speed 47 miles per hour, and the cut-off 50 per cent. With this superheat and cut-off at 25 per cent, it is reasonable to suppose that a water-rate approximating 15 lb. could be obtained. For this reason the desirability in future designs of superheaters is to produce, if it is possible, a superheater that will give us a uniform superheat regardless of the evaporation of the boiler. Until such a superheater has been produced the maximum economy and capacity from the boiler cannot be obtained under all working conditions.

C. J. MELLIN presented a written discussion on compounding and in commenting on the course of progress in steam engineering, he said it was but natural that the compound engine, which had been so successfully introduced into marine and stationary service, should find its way to the locomotive.

Difference in conditions under which the locomotive operates as compared with the marine and stationary engines, in that its greatest resistance is in starting, was not fully realized in earlier attempts to introduce the compound into railway service. Various means were later employed to compensate for this difference, but for many years the compound was looked upon with suspicion.

Very little improvement, however, was made in the simple engine until the compound commenced to show its superiority by handling heavier freight trains with the same weight on drivers as the simple engine and with a considerable reduction in fuel and water consumption, reduction in boiler repairs, improvement in smooth riding qualities, and the

practical elimination of jerks in starting, thus making a saving in car and draft gear repairs.

To compete with these advantages the simple engine was enlarged both in boiler and cylinder capacity, necessitating an increase in weight, and for a number of years the contest for supremacy was on, ending only when the limit of the right of way stopped the further enlargement of the low-pressure cylinder of the cross-compound engine; the permissible diameter being 36 in., or an equivalent to a 21-in. simple engine. The Vaucain four-cylinder compound, the four-cylinder balanced compound and the tandem compound followed, but all soon found their limitations.

The three-cylinder compound would have been the natural successor to the cross-compound but for the complications involved in applying the central main rod across the main axle, as was necessary on other than four coupled engines. Its introduction was, therefore, deferred indefinitely. Nevertheless, various designs of this type have been worked out to the equivalent of a 26-in. simple engine.

Instead of entering on this complication, a step still further in advance was taken about 12 or 13 years ago, when, after close investigation as to the best means of employing two low-pressure cylinders, the Mallet method of articulation was selected. The first design was made during the summer of 1902, retaining the American Locomotive Company's compounding system and American methods of construction throughout.

Up to this time there were few engines with higher tractive power than 40,000 lb. The bold idea of stepping up to 72,000 tractive power in compound gear and 86,000 in emergency was severely criticized. After long and serious consideration the Baltimore and Ohio Railroad decided to have an engine built to these proportions. Hardly had the engine started in regular service when its real qualities were discovered and its performance viewed with surprise. Reports of the result obtained caused personal investigations to be made by railway officials and resulted in a decided reversal of an unfavorable opinion to that of recognition of its advantages. At present 115,000 lb. in tractive power in compound and 138,000 lb. in emergency are being produced in very successful service and plans are worked out, ready when required, for engines of this type giving 140,000 lb. tractive power in compound and 168,000 lb. emergency power.

The next step for heavy power, where road conditions permit, is triple articulation, using the tender as the third unit. One engine of this type has been built having 160,000 lb. tractive power, but as yet it may be considered as experimental. On account of the limited boiler capacity on such engines, it may be necessary to make the tender engine independent of the other two units, subject to regulation at will, in order to get the maximum amount of steam for fanning the fire. The exhaust from the tender engine has very little effect by the time it reaches the stack and may therefore be carried direct from engine to atmosphere. Mechanical draft could probably be applied to advantage as a further means of increasing the boiler capacity at the slow speeds at which such an engine would naturally operate. By this means a tractive power of over 200,000 lb. could be obtained.

In the meantime the superheater has proved to be of great advantage in compounding. Practically all the superheat in the steam can be used before its final exhaust, and condensation during the latter part of its extended expansion is elim-

inated. This combination of compounding and superheating, when proper cylinder proportions have been observed, affords the greatest economy in locomotive operation.

Mechanical stokers have made possible the further enlargement of engines. It is also probable that mechanical draft in combination with a feedwater heater, will be an additional feature in the direction of economy, because of the possibility of running the boiler to its required capacity regardless of the speed of the engine. It also removes the unavoidable loss of power caused by back pressure in the cylinders, which loss increases with the size of the engine.

H. H. VAUGHAN, in discussing feedwater heating, called attention to the experiments that are being made with exhaust steam heaters, and waste gas heaters on the front end by Mr. Travithie on the Egyptian Railways. With the waste gas heater he has been able to put the water into the boiler at 250 deg. and obtain 22 per cent economy.

On the Canadian Pacific, experiments with open heaters in a tank have given fairly good satisfaction. We also applied exhaust-steam injectors to some engines and got fair results, but found that to operate them satisfactorily we should have an exhaust nozzle. We have since been advised by the manufacturers that our troubles were because of our having applied too large size an injector. While exhaust steam injectors work fairly well under certain conditions, yet there would be difficulties where the amount of water consumed would be large.

Experiments on an open heater showed that the temperature obtained from the exhaust-steam was due to the exhaust-steam from the feed pump. A temperature of 200 deg. in the feedwater is the equivalent of 160 deg. when water is put into the boiler by an injector with 100 per cent efficiency. By heating the water at the injection suction to 120 deg., we got 6 per cent economy using injectors, which we thought preferable to 10 or 12 per cent using a pump. Lately we have experimented with an ordinary closed feedwater heater.

Feedwater heating is a subject which railroad people on this side have neglected. It has the advantage of not only saving coal but increasing the capacity of the boiler, as the temperature of the water in the boiler would not be materially changed. My feeling about the heater is that we will see it coming into larger use not only with exhaust steam but with waste gas.

J. P. NEEF in speaking on firebrick arches and circulating supporting tubes stated that about ten years ago very few railroads were consistently using brick arches. A number of roads were tolerating them in a very small percentage of their engines, and a large number had discarded them entirely.

As the locomotive itself has been greatly improved during the last ten years, so has this particular device. It has been shorn of many of its original faults, leaving its never disputed virtues standing out all the more prominently.

Briefly, the arch insures more nearly complete combustion. The combustion of high volatile coal at the rapid rates necessary to meet the demands for large hauling capacity, is fraught with considerable losses due to incompleteness. That represented by the CO content in front end gases is only a part. Losses from incomplete combustion of hydrocarbons may easily be four times that represented by the CO per cent in the gas analysis. Anything that will mitigate

these losses without introducing too high air excess reflects at once in higher furnace temperatures. Combustion chambers help by lengthening the flame travel, but the arch, especially the arch on water tubes, not only doubles the average length of the flame travel, but in addition possesses the more important virtue of a mechanical mixer.

By enhancing combustion over the fuel bed, considerable more heat is involved and higher firebox temperatures result. Authentic tests have shown that with certain coals this increase in temperature may be 15 per cent. As a rule, these higher firebox temperatures are not accompanied with higher front end temperatures. Thus the double result of creating more heat and causing it to be absorbed, is accomplished.

Circulating tubes or arch pipes not only present the most effective heat transmitting surface, but the circulating effect is very important, especially at high rates of combustion. As the particles of gases must quickly touch the heat absorbing surface and give way instantly to other particles, so must the water on the opposite side of these surfaces, if a high rate of heat transfer is to be accomplished. Expedited circulation will insure this favorable condition. A locomotive boiler cannot give high duty per square foot of surface when the gases move leisurely.

Arch tubes, as they are now, give much aid, but there is still more to be done in this direction. Arch tubes or circulating water tubes through the firebox may be used in still greater number with good results, if properly arranged and disposed so as to aid in mixing mechanically and in circulating without too quickly lowering the temperature of gases.

G. W. RINK in reading a written discussion on valve gear and cylinders said that while every effort is being made to increase the efficiency of the boiler, it appears that the economical distribution of steam in the cylinders has also received some attention. In general, however, we are not getting the good results such as are obtained in good stationary engine practice. This is due to long steam ports and the use of a single slide or piston valve which has to control admission, cut-off, release and compression.

A design of cylinder overcoming these objections has been introduced in recent years and is known as the Hobart-All-free cylinder. A comparative test was made on the Jersey Central with an engine fitted with this type of cylinder and slide valves as against another engine fitted with the regulation cylinder and slide valve. These tests showed an economy in fuel and water consumption of approximately 12 per cent. Tests conducted on other railroads with Mallet engines equipped with the same style of cylinder and slide valve showed, with practically the same amount of coal per ton mile, an increase of 13½ per cent in tonnage hauled with an increase in speed of 4.3 per cent and a saving of water per ton mile of 11.1 per cent.

Valve gears have received a great amount of attention in recent years and a design which has apparently met with considerable success is known as the Baker valve gear. This gear was designed with a view of replacing the old inside link motion. It has also been applied in preference to the Walschaert gear in many instances owing to objections due to links or sliding blocks. The Baker gear has all bearings provided with pins and bushings which are more readily inspected and repaired.

W. E. WOODARD discussed detail design to secure reduced weight of reciprocating parts and other parts. He stated that in all designs it is necessary to get as large a boiler as possible, consistent with the proper design of the other parts of the locomotive. This leaves a certain amount of weight, in many cases, to be taken out of other parts, with the result that the designer scans all points where he can safely make a reduction.

In one case a systematic study of a design was made. As a result we found that 2500 lb. could be taken out without impairing the efficiency of the details or of the locomotive as a whole.

Cast steel cylinders offer a possible means of weight reduction, although they have not been used to any considerable extent. For large size locomotives, they would probably reduce the weight of the cylinders 3500 lb. per pair. There are a number of details, such as sand boxes, boiler fronts, etc., where material reductions can be made. We have been able to do much in the way of steel shakes for sand boxes. Wood cabs and wooden running boards can be used but there is a greater desirability in using steel.

Another thing is the question of changing steel worked out standards owing to new devices. I have under consideration the question of reducing the size of the cab. We have been able to reduce them from 84 in. and 90 in. down to 6 feet. The Pennsylvania has started on this line and we may see quite a little done in this way in the future.

H. V. WILLE in discussing use of high-grade alloy steels to reduce weight brought out the fact that many railroad metallurgists do not consider that the possibilities of high-grade carbon steel have been utilized to the fullest extent by designers. This is no doubt due to the fact that designers and metallurgists view the properties of steel from entirely different points. The metallurgist wishes a steel of great ductility with a good elongation and reduction of area, or in other words, a steel that will readily flow under limiting loads; whereas the designer desires a stiff steel, one of high elastic ratio or a steel that will not readily flow under loads above the elastic limit. The metallurgist therefore specifies a steel with a high elongation and reduction of area and to meet these conditions the manufacturer is compelled to use a steel of medium carbon.

As for possibilities of improvements, a decided reduction in weight as well as the elimination of failures would result from a modification of existing specifications for forgings for the purpose of permitting the use of steel of high tensile strength and elastic limit even at a sacrifice of ductility as measured by the elongation and reduction of area. These views are sustained by the results of an elaborate series of tests conducted by the United States Government at the Watertown Arsenal by Jas. E. Howard, on the endurance of rotating shafts. Enormous increase in endurance following the use of material having high elastic limit and tensile strength was notable and it was shown that carbon steel shaft exhibits as much endurance as 5.6 per cent nickel steel.

When steel forgings were first proposed for use in locomotives, a soft grade of steel was generally employed, the purpose being to secure a steel of similar properties to iron formerly employed.

The use of this material resulted in an unusual number of failures of axles, pins and rods. After studying these failures, Dr. C. B. Dudley, S. M. Vaulain and S. T. Wellman experimented with higher carbon steels. This led to the general adoption of steel of 80,000 tens. str. for locomotive work, with the result that the failures were eliminated and the great superiority of this steel over the softer steels was demonstrated notwithstanding the great difference between the two steels in elongation and contraction of area. This grade of steel is still being universally employed and any changes were for the purpose of increasing the ductility requirements rather than the tensile requirements, thus handicapping the manufacturer in the development of this grade of steel.

If specifications were revised to permit the use of a 0.65 carbon steel there would be but little necessity to employ the expensive alloy steels.

C. D. YOUNG in discussing the above subject called attention to the ordinary annealed carbon steel as used generally for locomotive forgings. The minimum physical properties may be considered as follows: tensile strength, 80,000 lb. per sq. in.; elastic limit, $\frac{1}{2}$ the tensile strength; elongation in 2 in., 22 per cent; reduction of area, 30 per cent.

With properly quenched and tempered carbon steel we may expect an increase in the elastic limit of 30 per cent or more, the elongation remaining the same and the reduction of area increasing about 15 per cent. These are conservative figures and a great deal better elastic limit and tensile strength may be obtained, depending upon the chemical composition of the steel and the heat treatment.

From alloy steels, such as chrome vanadium or chrome nickel, we may expect to obtain the following physical properties after heat treatment: tensile strength, 95,000 lb. per sq. in.; elastic limit, 75,000 lb. per sq. in.; elongation in 2 in., 20 per cent; reduction of area, 50 per cent.

On an average, these alloy steels will show an increase in physical properties over those of annealed carbon steel of 20 per cent or more in tensile strength, 80 per cent or more in elastic limit, with elongation in 2 in. about 9 or 10 per cent less than that of the carbon steel, and the reduction of area of 75 per cent or more greater. These figures are subject to modification on account of variation in the chemical composition of the steel and the heat treatment.

In carbon steel castings approximately the same per cent increases in physical properties as were given for carbon steel forgings may be obtained after proper heat treatment. The experience with alloy steel castings has been too limited to furnish any satisfactory data. Up to the present time the majority of users of heat treated steels seem to have made but little, if any, use of the increased physical properties as determining the fiber stresses used in design, though some of the larger builders of locomotives have made such increases in fiber stresses for both heat-treated carbon and alloy steels. In certain parts where heat treated carbon steel has been used, the fiber stress has been increased about 25 per cent above that used for annealed carbon steel, and in the case of heat-treated alloy steels an increase of as much as 50 per cent has been made. In some cases, depending upon the design and service for which the forging is intended, it is preferable to allow no increase in the fiber stress, but to consider the excess strength of the heat treated

material as contributing to increased life in service, or to safety.

Recent practice has indicated that it is desirable, when using heat treated designs, to study carefully the section, so as to avoid abrupt changes, and also in the cases of larger shafts such as axles or crankpins, that they shall be hollow bored in order to provide for better treatment and to relieve shrinkage strains which occur during the quenching process.

While there is no objection to the change of the present standard section, it would seem, with our present knowledge of heat-treated material, that it would be entirely safe to use certain increases in the fiber stresses when designing locomotive parts. As a suggestion as to what could be done in this respect, I have tabulated what is recommended for three grades of steel as to working fiber stresses and the minimum ultimate strength and elongation. This has been tabulated for the grades of 0.45 annealed carbon, quenched and tempered 0.52 carbon and quenched and tempered alloy steels.

The results shown in this table seem to indicate that heat-treated carbon and alloy steels will show greater resistance to wear and to the fatigue stresses in service than are shown by annealed carbon steel; and it is our opinion that the increase in resistance to wear is about in proportion to the increase in Brinell hardness which is brought about by the heat treatment.

C. F. STREET in a written discussion stated that stokers have not only increased the earning power of existing locomotives but have also removed all limitations, from a fuel quantity standpoint, on the size of locomotives which can be built.

Many instances could be cited of the increase in earning power of existing locomotives. Take the case of a saturated steam locomotive having about 54,000 tractive power and a tonnage rating over a certain division of 4750 tons. Superheaters were applied and the tonnage rating increased to 5000 tons. Stokers were applied and the tonnage rating increased to 5250, then 5500, then 5750 and finally to 6000 tons. In the meantime, the tonnage rating of the shovel-fired superheater locomotive increased to 5500 tons. The increase in the tonnage rating of the shovel-fired locomotives is very interesting and brings out strongly one of the indirect advantages of the stoker. It shows very clearly that before stokers were applied the shovel-fired locomotives were not doing anywhere near what they should do, and as soon as the stoker came into use, it increased the earning power not only of locomotives to which it had been applied but to all others on the division.

Reference to several of the locomotives mentioned in the committee's report brings out the fact that the stoker has removed limitations on the size of locomotives. The mountain types referred to were fitted with stokers when they were built and have always been stoker-fired. A number of other locomotives, notably the most powerful Pacific type as yet built, are now in regular operation and would never have been contemplated without a stoker. As high as 8 tons per hour have been put in a firebox with an existing machine and without working it to capacity. There is no reason why any desired quantity of coal cannot be fired by the use of a stoker and this limitation is entirely removed in connection with the designing of new locomotives.

The stoker, as yet, has not progressed far enough

to bring forth definite figures regarding its efficiency. Wherever it has been introduced the question of increased tonnage has been more important than that of fuel economy. This is only a temporary condition and as more stokers are applied the question of fuel economy will become more important. We have, however, gone far enough to determine definitely two points: First, the stoker will burn a much cheaper grade of coal than it is possible to use with hand firing; second, it will give a more uniform rate of fuel consumption on locomotives performing the same service.

It is a well-known fact that there is a difference of from 25 to 50 per cent in the amount of coal burned by different firemen for performing the same work. The stoker is eliminating this great variation and making the results more uniform.

There are today very few shovel-fired locomotives in this country having a maximum tractive power of 50,000 lb., or over, which are being worked to their full capacity. Wherever stokers have been applied the earning power of the locomotives has been increased from 10 to 20 per cent. There is no instance where stoker-fired and shovel-fired locomotives are being operated under identical conditions. The stoker-fired locomotives are in every case, hauling increased tonnage, using a cheaper fuel or working at higher speeds.

E. A. AVERILL remarked that in a report of a test on a large locomotive at the Altoona test plant it is stated that the results indicate that the capacity of the boiler was limited by the ability to burn the coal on the grates and not by any failure of the heating surface to absorb the heat supplied. While in this case the limit was marked by the impossibility of supplying sufficient air through the grates to burn the fuel properly, there are a reasonably large number of locomotives operating in this country today which are running at less than full boiler capacity because of the physical inability of the fireman to supply the amount of fuel that can be burned.

He said he had selected at random 10 classes of locomotives built during the past three years which are typical of the general size and capacity of all the larger freight locomotives built in that time. When delivering the power that each of these locomotives is easily capable of, if in good condition, it was seen that they required from 4900 to over 8000 lb. of good quality coal an hour. They are actually getting from 4500 to 5000 lb. an hour, and handling trains of a proportional size.

A number of locomotives like these, all of the same class, and operating on the same division, will have a tonnage rating in proportion to the ability of the average poorest fireman that is assigned to them rather than to the average best fireman. While there may be a few firemen on the division who are capable of developing the full boiler capacity, the group of engines as a whole may be daily working much below their actual capacity.

The acceptance of the opportunity to supply the desired quantity of coal at all times to these locomotives that is offered by the stoker, will have the same practical effect on operating expense as would a new order of more efficient, larger locomotives.

A reduction in the cost of conducting transportation follows this increased locomotive capacity in a number of the principal items when presented on a ton-mile basis.

The stoker itself offers an opportunity for further savings particularly in the cost of fuel, reduced claims for damage or accident and the recruiting of men of higher calibre for locomotive service.

An instance of the possible savings in the cost of conducting transportation, through increased locomotive capacity following the application of a stoker, is found on a certain division where 10 tonnage trains are sent one way over the road each day with hand-fired locomotives. Application of stokers has permitted an increase of over 11 per cent in the tonnage of a train. The return movement is largely empty. The application of stokers will give a direct saving from wages and train supplies alone, of about \$100 per engine a month on this division. If advantage is taken of the increased capacity of the division for tonnage without the addition of more locomotives, the saving will be considerably larger.

Naturally one of the first features to be investigated by a railroad considering the application of stokers, is the cost of maintenance. In general, the machine of any kind with the fewest parts, if they are properly designed, will cost the least for maintenance, inspection or repairs. During the past year and a half there has been a distinct advance made in connection with the simplification of the stoker apparatus. The latest type of locomotive stoker consists of a comparatively few, strong, heavy parts and a very few wearing surfaces.

There has been much discussion of the amount of coal consumed on stoker fired locomotives. In some cases they do burn more coal per trip and the mistake of making the comparison on pounds of coal consumed per 1000 ton miles has led to the deception of some investigators. Accurate tests permitting the comparison of shovel and stoker firing to be made on the basis of pounds of coal per indicated horsepower, have shown widely varying results with different designs of stokers. Some carefully conducted evaporative tests with the most recent design of stoker are very encouraging in this particular. These tests were made with the locomotive in regular service. Comparing the average of five hand-fired runs and four stoker-fired runs on the basis of actual pounds of water evaporated per 1,000,000 B.t.u. supplied, the stoker gave an increase of nearly 71½ per cent. In another case the increase in evaporation with the stoker was nearly 12 per cent. From these figures, as well as observations in regular daily service, it would appear that some saving in coal can be expected from this stoker. These tests were made with run-of-mine coal.

A stoker should successfully handle the coal in any condition in which it may be put on the tender. It should make no difference if it be all dust or clean lumps of larger size; soaking wet, slightly damp or bone dry. It should take the coal as it finds it the same as a fireman does. The development of stokers in this direction during the past year or two has been particularly satisfactory and ordinary run-of-mine coal is now being used with complete success.

The use of lower and cheaper grades of coal is quite general on the stoker locomotives of a number of roads which report a net saving from the practice.

Calculations that have been made of the movement of the gases in a firebox equipped with a brick arch, show that velocities of 265 ft. a second will be present over the end of the arch when burning 6000 lb. of coal an hour on 70 sq. ft. of grate area. The velocity decreases as the fire bed

is approached and at a point 2 ft. above the grate the gases have an average velocity of about 33 ft. a second. This clearly indicates the importance of injecting the fuel charge as low down in the firebox as possible to reduce the loss by fine coal passing through the flues partially burned. The more recent development in stokers has given this feature the attention it deserves.

Opportunities for economy in connection with the reduction in damage claims follow the better lookout from the locomotive by the fireman being left free to watch signals, crossings and operation of the machinery on the left side. One of the essentials in this connection is noiseless operation. The stoker should not prevent free conversation across the cab nor make any noise that can be heard when the locomotive is running. The development of the past year or two has shown a wonderful improvement in this particular and stokers are now being applied which are essentially noiseless in their operation.

The stoker should be 100 per cent efficient; it should do all the firing, handle all the coal from the tender with the minimum attention and not require alteration of the distributing means after it is once properly adjusted. The fireman should be free to attend to the duties mentioned above and should be able to control the stoker operation from a position on the seat box.

It is well established in manual firing that small quantities of coal fed frequently and distributed by the "cross fire" method gives the most perfect combustion. The stoker should follow this method but perform the operation more exactly than it can be done by hand.

Another feature of improvement in the most recent of the scatter type stokers is the absence of any part of the stoker on the boiler head or in the cab. Stokers are now being applied which show practically nothing in the cab and thus allow the best arrangement of the many instruments and appliances required on a modern locomotive. This also permits the proper inspection of all the staybolts and their renewal if necessary without the removal of any part of the stoker.

J. E. MUELFELD in a written discussion stated that the available energy in superheated steam, and the necessity for economy in first cost and for operation will cause the self-contained steam locomotive to remain for a long time the principal motive power for moving heavy tonnage trains long distances. For this reason, the next few years will probably see it substantially improved through the development of Mallet articulated types, superheating, compounding, feedwater heating and pumping, boiler circulation, valve motion gear, reciprocating and revolving parts, combustion, automatic stoking of pulverized fuels and standardization.

G. R. HENDERSON pointed out that 15 or 20 years ago it was thought that we had reached the limit of size and capacity in locomotives. Shortly afterwards we had some gain in compounding but we had large locomotives giving only from 1000 to 1500 h.p., whereas the size would have led us to think that we could get double that power.

Superheaters, coal pushers, firedoor openers, etc., have all helped to increase the capacity of the locomotive. In a few years we will very probably have largely extended the use of powdered coal. The present limitations of height

and width will not differ to a marked degree but the length can be increased without any special alterations except for turn tables and things of that sort where we can easily increase the length.

Our boilers can be increased in length, and there comes in Mr. McFarland's idea of an exhaust fan at the front end to give the necessary draft in the firebox. Powdered coal will help a great deal in assisting in lengthening the firebox and giving a greater amount of evaporative surface.

If we consider the present limitations of drawbar strength, length of siding, and legislative restrictions, I think by this lengthening it is possible to build a locomotive from 250,000 to 300,000 lb. tractive power.

J. B. ENNIS in a written discussion stated that 25 years ago the largest steam locomotive in service had a total weight of about 154,000 lb. and a tractive power of 34,000 lb. At that time, a locomotive of these proportions represented the improvement of 60 years of effort in this line of steam engineering, and while this advance had been gradual, it was a series of progressive steps leading up to the building of this "largest locomotive in the world." This 60 years of progress had been a period in which the main object seemed to be increased capacity only. Aside from the fact that the number of wheels was increased and the parts were made larger and heavier, a locomotive of this period in its essential details followed closely the established practice of years before. Detail design had been constantly improving, but at that time no general effort had been made toward improvement in the efficiency of the machine. A pound of drawbar pull meant the burning of the same amount of coal as it had a quarter of a century before.

During the past 25 years conditions have materially changed and the demands made on the locomotive have been such that the progress in its development was to be rapid. From 1889 to 1899 the total weight increased from 154,000 lb. to 232,000 lb. and the power in proportion. It was during this period that it was first realized that increase in capacity could not go on so rapidly unless accompanied by some efforts toward economy. The first general step in this direction was the introduction of the compound principle. Various systems were brought out and for years large numbers of these engines were built, many of which gave decided economies in service as well as increase in power. Although the movement to adopt this principle was advocated by many, the simple locomotive was still preferred and gradually increased in weight and power until it was thought by many that the limit of capacity had been reached.

Fifteen years ago, we find instances of locomotives built, where in order to maintain full power for any length of time, the amount of coal burned was so large as to call for considerable activity on the part of the fireman. Perhaps fortunately, stoker designs had not been perfected, although the time could not have been greatly delayed when consideration was to be given to other devices to bring about efficiency.

In Europe, superheating had demonstrated its economies in locomotive service and about ten years ago the first applications were made in this country. For some time its use was very limited, but after it was proven that high temperature superheaters would give increased capacity and great economy in fuel that would not be offset by high

maintenance expense, and that the economy could be obtained in all classes of service, the movement to adopt this principle became widespread. As a result of this improvement, combined with others that followed, we now have passenger and freight locomotives giving at least one-third more power at the drawbar than would have been possible 10 years ago with simple locomotives using saturated steam and consuming the same amount of fuel.

This increase in weight and power continued and the locomotive soon reached a size where it became necessary to consider, in many cases, some other means of feeding the coal than by hand. The mechanical locomotive stoker was demanded and produced. It is no longer an experiment and is capable of delivering all of the coal that the present day locomotive requires.

As examples of the big steam locomotives of to-day, we have simple freight locomotives giving tractive powers 50,000 lb. greater than the maximum of 25 years ago; an experimental articulated locomotive for pushing service designed to give a tractive power of 160,000 lb.; articulated locomotives for road or pushing service with tractive powers of 115,000 lb.; the simple pacific type with 46,500 lb. and simple mountain type with 58,000 lb. Individual wheel loads have steadily increased until we have nearly 70,000 lb. weight per pair of drivers. Our locomotives are as high and as wide as clearance limitations will permit, and yet it would be unwise to say that the limit has been reached.

The big steam locomotive of the future will probably not be the locomotive of the past. To-day we can see possibilities toward further refinement in design; further economies that may be obtained so that the locomotive designer is not yet ready to acknowledge that all has been accomplished.

For freight and pushing service on heavy grade, past performances show the adaptability of the articulated compound engine. This design of locomotive is still in the course of development and it will, without doubt, be the generally accepted type for these conditions for some time to come. With the exception of the experimental articulated locomotive already referred to, locomotives recently built for the Virginian Railway are the largest of the type. A few particulars of their performance may be of interest. Designed originally for pushing service on grades of over 2 per cent and normally rated at 115,000 lb. working compound, these engines have proven themselves capable of handling on a grade of 0.6 per cent a train load of 7180 tons, requiring a drawbar pull of approximately 110,000 lb. On lighter grades and at higher speeds over 3000 i.h.p. have been obtained. Work of this magnitude necessitates locomotives of exceptional weight and power, and yet the possibilities of this type have by no means been exhausted. As conditions arise in the future in which more power will be required, the use of the articulated engine can yet be extended.

For freight service on easy grades where the capacity of the articulated engine is not required, we already have exceptionally large locomotives of the 6, 8 and 10 coupled types. Simple cylinders operating at 200 lb. pressure have reached a diameter of 30 in., and in order to transmit this power a main axle 13 in. in diameter has been used. Main

crankpins, rods and other details are of enormous size. With the increase in the diameter of cylinders, the cylinder centers have gradually increased and frame centers decreased. This has resulted in higher stresses of parts than those caused by piston thrust only. The weight of revolving and reciprocating parts has reached the point where, in some cases, proper counterbalancing becomes very difficult. It is doubtful whether much more capacity can be obtained in these types if designed along the present lines, and here it would seem that attention could profitably be given to refinement in design and its relation to the careful selection of materials.

Modern passenger locomotives have reached a high development, and yet there is one problem still to be solved that has been recognized for many years—that of the effect on the rail of the vertical unbalanced forces in a two-cylinder engine. At present our largest and most powerful passenger locomotives have two simple cylinders 27 to 29 in. in diameter, giving maximum piston thrusts of approximately 117,000 lb., with static wheel loads higher than ever before and, with few exceptions, reciprocating parts of much greater weight.

The four-cylinder balanced compound was introduced about 10 years ago as a possible solution and for a few years a large number of these locomotives were built. There is no doubt as to the results obtained, as far as balancing was concerned, and yet recently very few have been constructed. Four-cylinder simple locomotives have also been tried out, but in both these types the capacity is limited on account of the available space between the frames, making it practically impossible to provide the power now given by the largest simple two-cylinder engines.

Little consideration has been given to the advantages of the three-cylinder arrangement, although a few locomotives of this type are in successful service today. As compared with the four-cylinder engine, either simple or compound, the three-cylinder type offers, first, the possibility of increased power. With one cylinder located between the frames ample room is provided for a properly designed crank axle and main rod which cannot be arranged for in the four-cylinder type beyond a certain limit. As compared with the two-cylinder engine, the advantages are briefly, a more even turning moment, an ideal counterbalancing condition and the opportunity to furnish maximum power with the minimum destructive effect on the rail. The power obtained in a two-cylinder engine with cylinders 27 in. in diameter and a maximum piston thrust of 117,000 lb. can be obtained in a three-cylinder engine with cylinders 22 in. in diameter and a maximum piston thrust of 78,000 lb. This decrease of 33 per cent in thrust means a corresponding reduction in the individual weights of all of the machinery, particularly the weights of reciprocating parts.

It is true that much progress can yet be made in the two-cylinder engine towards reducing the weights of reciprocating parts by the careful selection of materials and proper design. The three-cylinder engine, however, offers advantages possessed by no other arrangement, and it would seem that for high-speed passenger service, at least, this type is well worth considering for the future.

JOHN FRITZ MEDAL AWARD

ON Wednesday evening, December 2, the John Fritz Medal Board of Award conferred the John Fritz Medal for Notable Scientific or Industrial Achievement upon Prof. John E. Sweet "for his achievements in machine design and pioneer work in applying sound engineering principles to the construction and developing of the high-speed steam engine."

Very happily this event was arranged to occur during the Annual Meeting of the Society. The exercises were signally successful and thoroughly enjoyed. There was a large audience and a number of distinguished members of the four great national engineering societies were seated on the platform. Gano Dunn, president of the John Fritz Medal Board of Award, acted as presiding officer.

JOHN EDSON SWEET

Dr. Sweet's prominence as a national figure dates from his connection with the Sibley College of Mechanic Arts of Cornell University, in 1873. His connection with this institution lasted only until 1879, and in that brief period he rose from a position of obscurity to one of prominence, which he has ever since maintained. It was a case of the man and the hour. Mechanical engineering as a department of organized education was a new thing. In it there were no precedents, and regarding it there was almost universal skepticism. Its plans, its scope and its aims were unformed even among its friends, and its friends were few. Those who should have been its friends were largely doubters of its practicability, while among educators of the scholastic type it found no sympathy and less support. In its field there were, of necessity, no experienced educators, and perhaps it was best that there were none. The field was fallow, and into it came, almost by accident, the personality of this untried and unknown man.

His work was two-fold: first, that of a teacher, and second, of a pioneer in mechanical construction. As a teacher, the immediate results of his work will necessarily die with his students, but as a pioneer he laid enduring foundations. Previous experience in England had shown him the fundamental importance of the work of Whitworth, which, because of our then

JOHN E. SWEET, RECIPIENT OF THE JOHN FRITZ MEDAL

happy-go-lucky methods, had found little appreciation on this side of the Atlantic. Combining an appreciation of Whitworth's advanced standards of accuracy with original conceptions of fundamentally correct principles of construction of a kind far surpassing Whitworth's work, he established a school of construction of which the influence has been far-reaching. Along with this went an application of art in design—not the art of ornamentation, but the highest of all, and in engineering work the only true art, that of perfect adaptation to purpose—that has never been surpassed and probably never equalled. The Straight Line Engine was an embodiment of these principles, and from all points of view a perfect illustration of them.

Analysis of a successful teacher's methods is always difficult, and the greater the success the greater the difficulty. There is, perhaps, no field of human endeavor in which individuality has greater scope, as there is certainly none in which the methods of different, though equally successful, men differ more widely. Of Professor Sweet's methods there was little organization and less formality. For their prototype we must go back to the schools of the Greek philosophers, who gathered their students about them and taught by a process which was one of absorption rather than acquisition. Without compulsion, students gravitated to him as pieces of iron to a magnet. With few material aids and resources, and in that wider sense which consists of the training of the faculties and the formation of correct methods of thought and work, no finer example of educational work can be found. Those who came under its influence felt, and still feel, that they enjoyed a precious privilege. As a teacher, Professor Sweet was one of those few and rare, whose pupils became disciples, and to his success there is testimony that is unique—the informal organization of men, most of them beyond the meridian of life, who, calling themselves Professor Sweet's Boys, gather year by year on the occasion of his birthday, and from long distances, for an annual dinner with him at Syracuse. If any similar tribute is paid to another teacher the fact is not known.

Dr. Sweet was born October 21, 1832, at Pompey, N. Y., his mechanical talent being an inheritance through his mother. His introduction to mechanical

work was through his apprenticeship to the carpenter's trade, from which he developed as a builder and architect. In 1862 he went to Europe and for a time worked in England as a mechanical draftsman. Returning in 1864, the peculiar individuality of his work soon began to manifest itself, his most ambitious production of this period being a type-setting machine which is still preserved at Cornell University. Later, he was engaged in bridge building for Howard Soule, from which work he was drafted to the Cornell shop, where his pioneer work in accurate measurements was done. This with other examples of student workmanship was exhibited at the Centennial Exposition, where it attracted world-wide attention. The Straight Line Engine Company, with which his name has been identified, was organized soon after leaving the University. It was his suggestion which led to the organization of The American Society of Mechanical Engineers, of which he was the third President, nominations for previous years having been declined in favor of others whom he—mistakenly and characteristically—considered better fitted for the office. Other honors have been showered upon him, and always, as in the present case, against his protest. The most unselfish and helpful of men, and completely devoid of the spirit of self-seeking, he has found his reward in the unstinted esteem of his fellow men.

THE EXERCISES OF PRESENTATION

In his opening remarks Mr. Dunn said that the meeting was not so much in honor of Dr. Sweet as in recognition of the things which Dr. Sweet himself has done, which alone can justly do him honor. He then introduced the first speaker of the evening, Dr. James Douglas, past-president of the American Institute of Mining Engineers, who gave an address on the Development of Engineering in the United States.

ADDRESS OF DR. DOUGLAS

Dr. Douglas spoke particularly of the work of the engineer in the mining industry. The miner has always been more or less of an engineer. The primitive engineer was ingenious, and could install his own hoist and pump and if he had a running stream used the force of falling water to generate power and even compress air. With the introduction of the steam engine, however, came the need of the assistance of the engineer. For three-quarters of a century a very simple type of engine served the purpose; but within the memory of most of us there have followed in quick succession engines of elaborate design to economize steam, railroads, telegraphs and telephone, the dynamo, and electricity, applied to manifold uses. Each branch of engineering required a skilled expert in its application to mining and the engineering staff is now a distinct complement of the mining and metal-

lurgic members of every large organization in this field and are accepted as essential helpmates.

The engineering members of the modern mining and smelting plant outnumber those who direct the primary operations of the enterprise. On the roll of the Copper Queen Company, for instance, omitting the administrative and accounting officers, there are at headquarters a consulting engineer, with several expert mechanical and electrical assistants and draftsmen. Apart from them the mining staff consists of a superintendent, an assistant superintendent, a geologist and three assistants, three chemists, an operating electrician and 10 assistants, a chief mechanical engineer and 13 assistants.

In the smelting department of the same company, apart from the furnace superintendent, his assistant and two understudies, the officers are a mechanical engineer, an electrician and 12 assistants, a chemist and physicist and five chemists engaged in purely experimental work.

At both the mine and the smelter the power is generated in central works distributed by compressed air or electricity to hoist at surface, and underground; to power drills; to trolley lines; light circuits; to all of which more or less expert skill must be directed.

The power utilized at the mines is derived from 411,623,120 cu. ft. of compressed air and 321,539 kw-hr. The power generated at the Douglas Smelting Works is 3339.4 h.p. In mining, therefore, the amount of engineering supervision is out of all proportion to the quantity of power generated.

If we look beyond the metallurgy of the more costly metals whose value is in proportion to their scarcity, the demands upon the skill and energy of the engineer rises rapidly. On the average 83 tons of iron are consumed for one ton of copper, and when one traces the iron from the mine through the monstrously large smelting and rolling mills, where the metallurgist is almost obscured by the engineer, over the railroads to the stupendous buildings, where the iron is to be buried in concrete and brick to the amount of 10,000 to 30,000 tons per structure, one appreciates how intimate must be the alliance between the engineer and the miner and metallurgist.

Dr. Douglas referred to the metallurgical element in mining and metallurgical work. He came to the conclusion that the last person to select in this capacity is the expert, for if he is a trained mechanical engineer, mechanical devices will be too attractive; or if an electrical engineer, he will be emphatically an electrician, and so on. The manager should have instead just as much and as little knowledge of each branch as will enable him to select competent men and decide when a proposition is laid before him, presenting alternative methods, whose argument is most conclusive.

In respect to the future, in the light of the con-

servation of our resources, the speaker said that although it is not very difficult to estimate the date of the exhaustion of our ores at the present proportionate rate of increase, we nevertheless appear to be more worried about the consumption of our forests, which can be restored, than over the almost reckless consumption of iron, which rusts and vanishes. On the other hand, in respect to coal, we may be confident that long before the supply is exhausted, power, heat and light, and all that coal confers upon mankind will be derived from the transformation of other natural forces through the accomplishments of the physicists and the engineers, and that humanity will be relieved from the grimy work of delving underground for fuel.

ADDRESS BY DR. STRATTON

Following Dr. Douglas, Dr. W. S. Stratton, Director of the Bureau of Standards, Washington, D. C., ad-

of authority vested in it by the Constitution and absolutely necessary for the sake of uniformity in the measurements upon which all other forms of standardization depend. In other cases, it is interested in the standards and measurements used in the collection of duties and revenues, in the development and conservation of our natural resources, in the promotion of commerce and industry, and in placing its own work on an economical and business-like basis. To care for these interests, Congress established the Bureau of Standards in 1901. The Bureau does not assume an authoritative position except as to standards of measurement; in the other cases, its capacity is that of assistance in their establishment and advisory as to their use.

Standard values of constants enter into physical quantities, and are used in every branch of scientific work or industry. The amount of heat required to

THE JOHN FRITZ MEDAL IS A DISTINCTION FOR NOTABLE SCIENTIFIC OR INDUSTRIAL ACHIEVEMENT CONFERRED FROM TIME TO TIME IN MEMORY OF THE GREAT ENGINEERING PIONEER, JOHN FRITZ, AND THE AWARD OF THE MEDAL IS MADE BY A PERMANENT BOARD OF AWARD COMPOSED OF FOUR DISTINGUISHED MEMBERS FROM EACH OF THE FOUR GREAT NATIONAL ENGINEERING SOCIETIES

dressed the meeting on The Relation of Standards to the Development of Engineering.

He said that no greater tribute can be paid the honored guest of the evening than to say that he was a member of the small group of men who, in laying the foundation of modern engineering practice, introduced into it precision measurements. They made possible and introduced the interchangeable system of manufacturing, one of the principal factors in our country's industrial development.

For precision measurements are required certain standards which belong to the general group of Standards of Measurement. Other groups of standards may be roughly classed as Standard Values of Constants; Standards of Quality; Standards of Mechanical Performance; and perhaps Standards of Shape and Form. The government is interested in each of these but for widely different reasons. In some cases, principally standards of measurement, it is from the standpoint

change a pound of water into steam under normal conditions, and the relation between heat and mechanical energy, are two important physical constants; their values are used in practically every computation in connection with the designing of steam engines and boilers, the tests of their efficiencies or the measurements of their output. The amount of heat required to turn liquid ammonia into vapor or the amount required to melt a pound of ice are constants equally important in the refrigerating industries.

No one institution can accomplish more than a small part of the experimental work in this field. It is being done in government laboratories and scientific institutions throughout the world, hence the government is interested not only in the production of such data, but in gathering them together from all sources and in making them quickly available to the public as well as acting in an advisory capacity as to their use.

In considering standards of quality, it may be found

that a certain kind of steel, a cement, a paint, an oil, or a paper or cloth, is found by use to be good or poor. The questions then arise, what are the physical or chemical properties, or the particular combination of elements which make it of good or poor quality; how are its properties to be measured or its constituents determined. These are questions for the laboratory to answer and again involve scientific investigations of the most difficult sort.

The government is interested in this class of standards, partly from selfish motives in connection with its own purchases and construction, but principally from the broad standpoint of the public interest generally, just as it is interested in increasing the productiveness of the soil or in developing our mineral resources. The economical and proper use of materials is an exceedingly important factor in the great problem of their conservation.

The actual testing of materials by the government through its Bureau of Standards, to ascertain whether or not they comply with specifications, is confined almost exclusively to government purchases, but in making these tests, in which the Bureau has had the hearty coöperation of practically all the departments of the government service, it is compelled to make many investigations concerning the properties of materials, their specification and measurement. While this work is of great value in placing government purchases on a correct basis, the results of the investigations as to the properties of materials and the information gained in testing government supplies, is even more important to the general public.

In respect to standards of performance, the performance of an engine or boiler, a pump, an electrical generator or motor, a weighing device, or a telescope, can usually be measured, but the quantities to be measured and the method used must be specified correctly, and understood by all concerned in the construction, purchase, or use of such apparatus. To do this properly involves the use of standards of measurement, standard values of constants, and standards of quality. The Bureau of Standards does not attempt to cover this field completely, but only those cases where there is a lack of definite scientific data upon which to base specifications, and to the more important classes of apparatus.

Again, the Bureau's activities in this field have been principally in connection with government purchases of apparatus and machinery. Government purchases of equipment, however, are not greatly different from those of the public. Whenever the Bureau makes a scientific investigation or secures such information from other sources for the purpose of the improvement of specifications, it is given to the public in the form of suitable publications. The value of this from the standpoint of the public is even greater than that in connection with government purchases, important as

the latter is. In other words, the needs of the public and the government service are precisely the same as far as standards or specifications are concerned, whether it be standards of measurement, quality or performance.

Many questions of disagreement between public officials and utility companies as to standards are referred to the Bureau for advice or adjustment. There is a great need for unbiased and reliable information pertaining to the standards entering into the regulation and sale of the services of public utilities. A striking illustration is to be found in the various state regulations pertaining to locomotive headlights. Some regulations require that headlights shall not be less than 1500 candlepower when measured without a reflector; others specify 10,000 candlepower measured with a reflector. Some states require 300 watts at the arc, while others require that an object the size of a man shall be distinctly seen at a specified distance (they do not state the color of the object), and one state specifies the size of the reflector. There are plenty of such cases.

Some of these regulations are almost as absurd as the law proposed by a Western legislator to make the ratio between the circumference and diameter of a circle the whole number three; or another who, when told that the law of supply and demand interfered with some proposition in which he was interested, introduced a resolution repealing that law.

The Bureau's investigations in connection with the distribution of high potential electric currents, the mitigation of electrolysis, the fire-resisting properties of materials, the standards involved in the regulation of gas service, and the causes of failure of railway materials, are all examples of investigations that are being carried on by the Bureau with a view to ascertaining the fundamental facts needed in making public utility regulation sensible and fair. No doubt the question has already arisen in your minds as to whether this work competes or interferes with that of the engineer; on the contrary, these investigations are for the purpose of ascertaining the very information the engineer needs. The Bureau prefers to work through the engineer. Whenever it comes in direct contact with public officials in such matters, the Bureau encourages the employment of competent engineering services. There are many cases in which it would be far better for those concerned to employ more technical and less legal advice. The Bureau's coöperation with engineers and manufacturers is another important phase of its work.

The value of such minute measurements is sometimes questioned, but they are necessary for the detection of laws or measure constants, which will make it possible to make accurate measurements with even the accuracy required in industrial processes. In the past three or four years one of the Bureau's experts has been engaged in perfecting the instruments used in measuring total radiation, in order that he might determine

among other things the radiation constants with sufficient accuracy for use in the industrial measurement of high temperatures. Recently one of these instruments was used successfully at the Lick Observatory to measure the radiation from stars as faint as the seventh magnitude, or, in popular terms, equivalent to the detection of the radiation from a candle flame fifty miles away.

PRESENTATION ADDRESS

John R. Freeman then spoke on behalf of the Board of Award. He touched in his remarks on the life of John Fritz, saying that he left the art of iron making better than he found it and furnished an example which must be an inspiration to all. The John Fritz Medal was founded on Mr. Fritz's eightieth birthday. The principal rules for its award, as adopted, are that it shall be given for notable scientific or industrial achievement, after consideration by the Board of Award for one year. The Board itself is composed of sixteen members, chosen in equal numbers from the four national engineering societies, the American Society of Civil Engineers, the American Institute of Mining Engineers, The American Society of Mechanical Engineers, and the American Institute of Electrical Engineers.

Eight awards of the medal have been made: in 1905 to Lord Kelvin; in 1906 to George Westinghouse; in 1907 to Alexander Graham Bell; in 1908 to Thomas A. Edison; in 1909 to Charles T. Porter; in 1910 to Alfred Noble; in 1911 to Sir William H. White; in 1912 to Robert W. Hunt.

Mr. Freeman concluded his remarks with the following tribute to John E. Sweet:

To-night the medal is to be bestowed upon the one who more than any other one man now living brought about the forming of The American Society of Mechanical Engineers—to one who years ago as a college professor quickened the life and human interest of many men now no longer young—to one who pioneered in high-speed steam engine building and taught the necessity of precision of workmanship and of opposing stress with metal placed directly along the

line of force, if one would double or treble the work to be performed per pound of metal.

Like John Fritz he comes to our meetings as Holmes said, "not 82 years old but 82 years young." His presence brings to mind the words of the poet of Abou Ben Adhem, who begged of the recording angel to at least "Write me as one who loves his fellow men," and who later saw

"The Angel writing in the book of gold

The names of those whom love of God had blest.

And lo, Ben Adhem's name led all the rest."

We bestow the medal upon one whose life has been lighted by a sweet and kindly ideality. Engineering, dealing with hard structural materials, by rigorous theorems, may seem to some to give small place for ideality. Kipling gives a glimpse of the other side, in McAndrews' Hymn.

Poets and painters have hardly excelled in ideality our great engineers working for the good of mankind: for example, Westinghouse dreaming of safer transportation and the manufacture and distribution of power for the service of man; Edison in bringing music to the humblest home; Brashers, Swasey and Warner working in their machine shops have brought the precision of machinery, by application in astronomy, to uplift the soul of man; Leland in that kindness of heart and love of good workmanship which leads him not only to build the best he knows, and to prize good tools as pictures in steel, but also to gladly help his competitors; Taylor, not always understood, working to improve the understanding between labor and capital, by striving always to bring the workman to higher usefulness; and Hiram F. Mills devoting thirty of the best years of his life without thought of compensation, and as an act of religion, to found the profession of engineer of public health. This kind of man is also illustrated in Alexander Lyman Holley, Hoadley, Trautwine, Loammi Baldwin whose wonderful library of ninety years ago marks the idealism of the "father of Civil Engineering in America," also by Crozier, Hartness, and a hundred others whom we cannot now particularize.

And to this noble army of idealists belongs the friend whose faithful work we commemorate to-night, the manufacturer, who chiseled in stone over the doorway of his works, "Visitors always welcome."

The meeting closed with the formal presentation of the medal by Gano Dunn "to John Edson Sweet, ripe in years, ripe in honors and ripe in the respect and affection of the whole engineering profession."

DISCUSSION OF THE BOILER REPORT

The importance of the problem that has arisen in the formulation of the report of the Boiler Specifications Committee was again emphasized by the attention that was given to the discussion of the Progress Report (fourth printing) that was issued by the Committee before the Annual Meeting. The report was brought up for discussion at the regular business meeting of the Society at the Wednesday morning session, December 2, and monopolized the remainder of that session until adjournment at 1 p.m. The discussion was adjourned to a separate session in the afternoon and after that to an evening session. On the next day the discussion was continued all day, and was concluded with a five-hour session on Friday, December 4, making a total of six separate sessions, aggregating 20 hours of continuous meeting devoted exclusively to the discussion of the Boiler Code and the work of the Boiler Committee.

At the first session, the business meeting of Wednesday morning, the report of the Committee was brought up in open meeting in accordance with the regular procedure of the Society of discussing all important matters in preliminary form before their final presentation. John A. Stevens, Chairman of the Boiler Specifications Committee, opened the subject by a short address. He called attention briefly to the need for the Boiler Code which the Committee is at work upon and outlined the development of the work up to the present time and the methods that had been provided for all who had further suggestions or criticism of the report. He urged them to submit any suggestions to the Committee at this meeting and in that way to cooperate in facilitating the production of the final report—a matter of the greatest urgency at the present time in view of the need for a definite code which will permit the standardization of boiler work in all parts of the country.

In opening the discussion the President ruled that consideration should be given to the details of the Construction Code only, each subject involved and each paragraph to be taken up serially throughout the book, wherever discussion might be offered. This ruling brought objections from some members, however, and contrary to the proposed procedure, the President entertained a discussion of the general considerations of the report as a whole. A limited amount of unfavorable criticism was made by some who raised objections to the method of procedure carried out by the Committee and by others who objected to the general proposition involved in the Committee's work in so far as it involves proposal of legislation. Considerable discussion followed this, in which the great majority favored the general plan and commended the Committee in its work. Several attempts were made to resume the pro-

posed plan of discussion of the report paragraph by paragraph, but there was no concerted effort made to do this until after a motion to discuss the report as a whole, was voted upon. This gave those who were not in sympathy with the purpose of the Committee's work an opportunity to express their opinions and a vigorous argument as to the merits of the form of code proposed, its effect upon the boiler industry, its advisability and desirability, etc., followed. Finally, a strong attempt was made to bring a motion before the meeting that would test out the points of advisability of continuation of the Committee's work, but the motion was curbed by numerous amendments and was finally delayed by the adjournment for the noon recess.

The meeting reconvened at 2 p.m., at which H. G. Stott, Vice-President of the Society, presided. The motion that was before the meeting before it adjourned was withdrawn, and the discussion of the Progress Report began as had at first been planned. It began with page 27 and was continued with careful detailed attention to each paragraph. The criticisms ranged from minor points of punctuation or grammatical arrangement to questions of correctness of the rulings, consistency of the various requirements, and other items of engineering significance. For example, the safety valve requirements which had been approved at a conference of safety valve manufacturers in cooperation with the Boiler Committee and had been considered an important advance in this direction, were not well received by practical men: they were strongly criticized by those who had had actual experience in inspecting boilers, on the ground that they were too complicated and cumbersome for convenient use and also because the method of basing the steam producing capacity on the heating value of the coal would in certain cases require larger safety valves to be applied if boilers were to be moved to states where different fuels would be encountered. The criticism on the modified requirements of this section was so strong that it was decided to refer the entire problem back to the safety valve conference, at which the requirements were proposed.

The remainder of Part I of the Rules for Construction were passed through with a fair rate of progress, detailed attention being given to such questions as fusible plugs, steam and feed piping connections, water column connections, etc., but the argument on the validity of the Tables of Joint Efficiencies was delayed until later. The second session was then concluded with a discussion of Paragraphs 84 and 85 on page 188, relating to the question of welded joints in shells. This resulted in suggestions for slight modifications in wording.

The third session, Wednesday evening, began with a general discussion of the material specifications that

comprised pages 189 to 212 of Part II. Efforts have been made to bring these specifications into complete harmony with those of the American Society for Testing Materials. It appears, however, that the specifications in their present form, are acceptable to that Society, but where there are minor differences present, it is not unlikely that modifications may be made in the American Society of Testing Materials specifications so that they will agree with this group in all particulars.

It was shown, however, that the group of specifications in the Progress Report should be amplified by the addition of further specifications to cover iron rivets, staybolt steel and bar iron and bar steel. This matter was referred to the committee representatives of the steel manufacturers, with instructions to select specifications from the American Society of Testing Materials standards which would cover these requirements. Considerable discussion ensued relative to the form which these specifications should take and the proposed modifications, but no definite action was taken. The new tube specification which was the result of the first complete conference of boiler tube manufacturers in America was favorably commented upon.

The material requirements of the Code were then discussed and extended consideration was given to the matter of the quality of boiler steel specified for the various portions of boilers. This important part of the Code was discussed here more thoroughly than it had been in any other conference or hearing that had been held by the Committee. The result was a complete modification of this section and a final settlement of the question in such a manner as to satisfy entirely the various associations and interests involved. In general, the ruling now stands that furnaces, shells, combustion chambers, or any part of boilers under pressure and exposed to the products of combustion, are to be made of the firebox grade of steel. The other requirements were also revised into better form and made complete by additions to cover a number of other materials used in boiler construction.

The fourth session, on Thursday morning, was devoted to continued discussion of the Rules for Construction section, from page 215 to the end of the Code. In this section, such topics as maximum allowable pressure, efficiency of ligament, staying of heads, dished heads, staybolts and other subjects of kindred importance were considered in great detail, and in the course of the discussion, many minor differences were brought up and argued to satisfactory conclusions. Among these was the case of the lap seam for boilers, which, while manifestly unsuitable for power boilers, was amply strong and offered unmistakable advantages for heating boilers. The result of this discussion was the suggestion that the requirements for heating boilers be segregated in a section entirely distinct from the power boiler rules, so that the particular requirements of this class of boilers can be adequately treated. This matter

was referred to a representative committee of heating boiler manufacturers for further study.

The various requirements that tended to limit the sizes of boilers or to enforce unnecessary hardships on manufacturers, received careful attention. The lengths of plates permitted in horizontal return tubular boilers, and the question of lap joints on domes, were decided upon with slight modifications. These were of decided advantage to the manufacturers of small boilers. The clause limiting the length of longitudinal joints was stricken out and that referring to the process of forming butt straps radically modified. Some discussion was given to forms of expression, used in connection with this section of the rules, and many suggestions were made to obviate the possibility of ambiguity in the various rules.

In the afternoon session on Thursday, a variation in procedure was admitted for the convenience of certain members who found it necessary to leave the city that night and who wished to discuss the Recommendations on page 255. Arguments were offered against Paragraph 1 on that page, for the reason that it would limit the size of horizontal return tubular boilers below what is considered by some as good practice. After an extended expression of views, a revision of this paragraph was agreed upon which seemed to relieve the difficulties, to obviate which this paragraph had been drawn.

Following this, some discussion was participated in as to the advisability of the so-called Recommendations Section of the Code, which has been omitted in the Massachusetts Code. The chairman of the Committee explained at great length the purpose and advantages of such a section, and pointed out how better practice might thus be influenced by the moral effect of such Recommendations, which would not, however, have the injurious effect of enforcing hardships upon those for whom they were not intended. As a result some further corrections were made and Paragraph 12 was shown to be of such importance as to warrant its transfer to the main body of the Rules, but no further suggestions were received.

After this, the attention of the meeting was again given to the Rules, beginning at Paragraph 150, page 224 to page 245. The subjects taken up included staybolts, staying heads of boilers and segments of heads, riveting, galking, manholes, settings, valves, feed and blow-off piping, and the provisions for non-standard and second-hand boilers. Many of these points were extensively discussed and some changes were agreed upon for the improvement of the rules in their practical application.

At the sixth and closing session, Friday morning, December 4, at which Vice-President I. E. Moulthrop presided, a few points were taken up which had been passed over rather hurriedly in the previous session, particularly in connection with feed piping, point of entrance of feed water to boiler, etc. The requirement

calling for a stop cock between the check valve and the boiler proved very objectionable to some, and there was an extended debate on the question and a vote of the meeting was necessary to settle it. The question of blow-off piping was taken up again and then steam piping, water columns and their connections to the boilers, and the factors of safety of non-standard and second-hand boilers. It was voted that the questions of factor of safety and age limit be referred to a committee consisting of Prof. A. M. Greene, Jr., chairman, Prof. Wm. Kent, Frederick Sargent, F. H. Clark, Thos. E. Durban and H. G. Stott. Another action of importance was a resolution authorizing the transfer of the entire section at the back of the Progress Report referring to stays and furnaces, pages 259 to 267, to the body of the Code, starting on page 233.

The final work of the session was in connection with the matter of the advisability of retaining the tables of efficiencies of riveted joints. There was heated argument which extended to the origin of the tables, the reasons for including them, their practical value, etc. A motion was then made to the effect that a new set

of tables should be prepared, using the tensile strength of 55,000 lb. only and the new revised shearing strength values for the rivets. This was put to a vote and carried. Various other details of the proposed modifications in the tables were discussed and settled by vote, and a committee was appointed to redraft the tables.

The final action of the session was the discussion of the policy of procedure in further revision of the report, in which a strong sentiment developed for the elimination of the features of laws and legislation from the report. This seemed to be necessary to bring the Code into acceptable shape for several of the bodies interested in its promulgation. A motion was made to express the sentiment of the meeting, which directed that the Code be redrafted so as to eliminate all legislative requirements and concentrate upon technical rulings and engineering features only. Before adjourning, some time was spent in consideration of the matter of the further revision, the receipt of further criticism and suggestions. The Committee made another appeal for constructive assistance which would tend to make the Code the best that could possibly be produced.

FOREIGN REVIEW AND REVIEW OF PROCEEDINGS OF ENGINEERING SOCIETIES

ENGINEERING SURVEY

With the present issue, the Engineering Survey enters into the second year of its existence in its present enlarged form, and the Editor takes this opportunity to acknowledge gratefully the many letters of kindly encouragement and useful suggestions received in this connection.

A new system of headings for the articles in the Foreign Review section has been introduced in this issue, the title of the article being prominently printed in the center of the headline, and a brief summary of the article being given in the next paragraph, so as to enable the reader to see at a glance what the article contains. The reference to the source from which the article has been abstracted, has been relegated to the end of the abstract. In view of the fact that of late numerous orders have been received for having articles which are abstracted in the Engineering Survey photographed from the originals in the files of the Library, the number of pages that would have to be paid for if ordered for reproduction, is indicated at the end of the article.

The Library of the Engineering Societies, as part of its work compiles bibliographic references on various engineering subjects. It is proposed, from time to time, to reprint such bibliographies when the abstract of an article covers a matter of sufficiently general interest on which a search is available. This month, such a search is given on the subject of waterproofing concrete.

THIS MONTH'S ARTICLES

Data on the combustion of benzole in internal combustion engines are given from an article describing the work done at the Technical High School at Karlsruhe. The next abstract describes an interesting Pelton turbine installation which is said to use the largest jet so far applied. In the same section there is a description of a water level indicator by which it is possible to discover variations as small as 0.078 in., and which can be read at a distance.

The section on Mechanics contains several abstracts of interest on the experimental determination of the uniformity of running of prime movers; flow of oil in pipes; torsion strength of reinforced concrete beams; application of the principle of Saint-Venant to the solution of problems on beams; the principle of variation in the theory of elasticity.

A description of an improved surface cooler and data on a centrifugal machine for drying sludge are found in the closing sections of the Foreign Review.

Excessively dry air in cold stores is the subject discussed by Wm. D. Sawers before the Cold Storage and Ice Association. Data on Chinese concrete, and on the difference between steel and iron reinforcing elements, hooked bars and straight bars and other data are presented in a report of a committee of the Engineering Society of China.

The application of the counter-current principle to directly fired and waste heat boilers forms the subject of the paper of George H. Gibson before the Engineers' Society of Pennsylvania. The author arrives at some interesting conclusions, on the use of economizers especially, which are at considerable variance with the view usually held.

The testing, and some particulars of construction, of a large reversible rolling mill is described by Karl Nibecker in a paper before the Engineers' Society of Western Pennsylvania. The tests have shown an inordinately large loss of power in accelerating and retarding the engine parts, but a very low loss of power due to friction, and indicates several other features of interest to the engine designer and rolling mill man.

The paper of F. A. Weymouth on typical rail failures describes various causes of rail failures, gives a classification of defects, and discusses the so-called frictionless rail. Another paper dealing with steel structures, in this case ship plates, is that of W. J. B. Wilson, where a remarkable failure of a consignment of such plates is described, and it is shown how unreliable the indication of the usual methods of investigation and testing may prove to be in some cases.

Two papers abstracted from the Journal of the Western Society of Engineers, treat of the characteristic curves of centrifugal pumps, and of permeability tests on gravel concrete.

FOREIGN REVIEW

Hydraulics

WATER TURBINES ON THE BORGNE RIVER PLANT.

The article forms part of a series describing water turbines and their governors. In particular, it describes a Pelton turbine delivered by Escher, Wyss & Co., for the Borgne River plant of the Aluminum Industry Co. of Neuhausen. It is remarkable both on account of its size and its design.

The water is delivered to the turbine by pipes 900 m. (2952 ft.) long and 1100 mm. (43.3 in.) average diameter. These pipes are lapwelded by hydrogen flame. The turbines are rated at 7500 h.p., with a maximum output of 8250 h.p. at speeds of 273 to 300 r.p.m. The exciter turbines have an output of 600 h.p. at 800 r.p.m. The turbine is shown in Fig. 1 A. It has a runner of 2.5 m. (98 in.) theoretical diameter and a single nozzle out of which, with needle fully withdrawn, issues a jet 0.2 m. (7.8 in.) in diameter. This is the largest jet hitherto applied. Fig. B shows the way the blades are held. Each blade is held by two staggered ring elements and supported against the next blade, so that the bolts have only the purpose of holding the segments together. The runner is made entirely of steel casting. All parts of the turbine which are subject to normal wear are installed in such a manner as to be easily and quickly exchangeable. A steel shaft is supported on two lubricated ring bearings, symmetrically disposed with respect to the center plane, while collars are provided to take up the axial thrust; each bearing has two lubricating rings and an oil circulation pump which sends back to the bearing the oil flowing away from the cooling pipes.

Fig. A indicates the needle nozzle with the needle and its appliances, jet deflector and the mechanism for moving the governor. On the same level with the turbine shaft to the left, at a distance of 2150 mm. (84.6 in.), is located the governor shaft driven by the universal oil pressure regulator. This shaft actuates the entire regulator mechanism. The

indicator apparatus. Therefore three conductors with a grounded return circuit are required, as shown in the sketch. The indicator apparatus is provided with a six-roller motor, consisting of six single-coil circularly disposed electromagnets, the pole shoes of which are directed radially inwards at angles of 60 deg. Each pair of electromagnets is connected in such a manner that the opposite pole shoes should form opposite poles while in the intervening space. There is an easily rotatable axis carrying two soft iron armatures and transmitting its motion to the indicator axis.

If the float causes the switch wheels of the apparatus to rotate, in either direction, the three contacts are moved one after another in such a manner that the next contact is always closed before the contact previously closed is thrown open. In this way, one after another, the three pairs of electromagnets of the indicator are first excited and then left free of current and the armature is forced to rotate in the same sense as the axis operated by the float. A constant

internal combustion engines and covers the matters of load compression, ignition and air supply.

The incentive to carry out this experimental investigation was given by tests on heat balance of a 3 h.p. liquid fuel Otto engine, carried out in the mechanical laboratory of the technical high school at Karlsruhe. During these tests, it was found that a fairly considerable amount of energy given to the engine could not be traced and it appeared that this heat loss could be caused only by incomplete combustion of the fuel in the motor as well as conduction and radiation. Even though the constructive part of combustion engines has been well developed and they belong to the class of engines most reliable in their operation, still a good deal remains to be found out with reference to the combustion processes in the motors. It appeared, therefore, of interest to investigate as to how far incomplete combustion contributes to the errors found in the heat balances and how they are affected by the variations in load, compression, ignition and the

FIG. 2 WATER LEVEL INDICATOR

current flows through the conductors with a small amperage of only about 0.035 amperes, current being provided by a special battery. Atmospheric discharges have scarcely any influence on the operation of the indicator since at all times there is a pair of electromagnets operated by the line current and the armature tends to remain in any position which it has. A further advantage in the application of open-circuit current lies in the fact that should there occur a break in the conductor or should the battery give out, an alarm circuit will be closed and will at once indicate the trouble. Should it be desired, the indicator can be equipped with a recording apparatus which will show the level of water by a curve on a drum in the usual manner. An apparatus of this type is used in the city works of Gotha, Germany. (*Elektrische Wasserstandsfernmelderinrichtung für Feinanzeige*, Georg Schmidt, *Zeits. für gesamte Turbinwesen*, vol. 11, no. 29, p. 429, October 20, 1914, 3 pp., 4 figs. d).

Internal-Combustion Engineering

COMBUSTION OF BENZOLE IN INTERNAL COMBUSTION ENGINES.

The article presents tests on the combustion of benzole in

amount of air of combustion. Products of incomplete combustion are to be looked for in the form of combustible particles in exhaust gases in the condensing water of combustion and in soot deposits in the cylinder. The formation of soot has been very small in all of the tests carried out and its determination therefore could be neglected. The same applies to the case of combustible materials in the water of condensation. It is well-known how few investigations of exhaust gases on engines have been carried out. This may be due to the fact that a chemical investigation of special mechanical problems is too seldom undertaken.

From the investigations of Slaby and Haber, the author proceeds to a brief sketch of the work of Weber, Eugen Meyer and Brook Sewell. More recently, Häuser has determined the heat losses through the exhaust gases of a gas engine in the form of unconsumed material. He used the method of combustion over copper oxide, while Haber and Weber attempted to determine the quantitative combustion of exhaust gases. Häuser considers the method of Haber unreliable since there is not always enough oxygen in the exhaust gases to fully consume the unburned particles. All of the above investigators have found that the amount of

combustible material in the exhaust gases of gas engines does not attain very high values and so far as the influence of load can be considered, it was found that the engines work better at full load.

As regards the kind and amount of combustible particles in the exhaust gases of internal combustion engines using liquid fuel, there are no investigations with the exception of an unpublished thesis by Rudolph Mayer (Karlsruhe, 1909), who has determined volumetrically the percentage of carbon dioxide, oxygen and carbon monoxide, but his data are not claimed to be particularly reliable since his gas samples were not carefully taken average samples and the investigation of the gas was carried out as a side line.

Benzole is not adaptable for use in Diesel engines on account of its endothermic character. It can be only imperfectly changed into oil gas and its compression to the point of self-ignition involves great difficulties. As regards explosion engines, benzole, although it boils at a fairly low temperature (79 deg. cent.), and although the explosion limits of benzole vapor-air mixture are nearly the same as those of gasoline vapor-air mixture, a benzole driven motor has been developed only after considerable trouble, one of the main difficulties having been that of overcoming the tendency of benzole to form soot deposit. It was necessary therefore to investigate the combustion of benzole in engines and it is to this problem that the present experiments have been devoted.

The article describes in some detail the experimental engine and installation. The compression space of the engine could be varied by placing on the piston rod head intermediary pieces so as to increase the compression. The gasification of the benzole was effected by means of a vaporizer illustrated in the original article. It is virtually a needle gasoline vaporizer and does not present anything special in its construction. The Brauer crank mechanism was used to drive the indicator drum.

As regards the collection of exhaust gases, the first attempt was to collect them in a tank filled with water into which they were brought by suction by means of a descending water column. This method proved to be inconvenient on account of the great solubility of the gases in water. Considerable improvement was introduced by determining at the engine the percentage of carbon dioxide which forms the most soluble part of the exhaust gases. To do this, the exhaust gases were passed through two washing bottles, in which, also, the water of combustion carried with the gases was kept back. Then the gases were dried by calcium chloride and anhydrous phosphoric acid, and led into the apparatus for the determination of the carbon dioxide consisting of a Geisler sodium apparatus with KOH 1:1, as well as pipes with calcium chloride and anhydrous phosphoric acid; behind the latter were placed an unweighed protective tube filled with calcium chloride. The gas freed in this way from carbon dioxide was then collected in a gas holder provided with a thermometer, manometer, admission and exit pipes over water.

Later on this method of work, still quite complicated and liable to be a source of errors due to the solubility of gases, was simplified by the use of a mercury gasometer whereby the precision of the analysis was very much enhanced.

The author proceeds to the discussion of the method of gas investigation. Dry exhaust gases consist of carbon

monoxide, carbon dioxide, hydrogen, methane or hydrocarbons, oxygen and nitrogen. The analyses made and given in table 1 correspond to three loads at maximum compression. They are, however, only of a preliminary nature. It was found that heavy hydrocarbons are but seldom met with and then only in small quantities consisting mostly of acetylene and sometimes traces of benzole. Only in the gas in a test on 10 kg load, on defective ignition, it was found that because of the defective ignition due to sooted spark plugs, an excessive amount of hydrocarbons was formed; notwithstanding the presence of free oxygen, considerable quantities of acetylene and traces of benzole remained unconsumed.

Of particular interest also, is the presence of methane in the exhaust gases of benzole fired engines. More about this will be said later. It was found, however, that volumetric analyses were not sufficiently precise for the determination of heat losses as unconsumed material in the gas. The author resorted therefore to gravimetric determination in which he could have used three ways: the fractional combustion method of Bunte-Haber-Weber; fractional combustion method over copper oxide and total combustion over copper oxide at red heat. Experiments have shown that because of the small amount of acetylene and benzole present side by side with methane in the exhaust gases, the fractional combus-

TABLE 1 EXHAUST GAS ANALYSIS

CH ₄	0.2	0.24	0.5	0.25	0.44	1.4
N ₂	81.1	78.36	76.62	77.15	74.79	72.5

tion method is not applicable and a total combustion method over copper oxide was used; the products of incomplete combustion in gas, freed from carbon dioxide and water vapor, were completely burned to carbon dioxide and water over copper oxide at red heat and the amounts thus produced were determined analytically. Although this method gives no information as to the constituents of the gas, it was used here because what was of interest to determine was the heat lost in the form of unconsumed material. The author shows in detail the construction of the apparatus which he used. He also calculated the limit of error and found that it was such as to be entirely negligible in comparison with the amounts of carbon dioxide and water produced.

As a basis of all tests on output where a complete heat balance is used, an exact knowledge of the elementary composition and heat of combustion of the fuel must be considered. In the tests, two kinds of commercial benzole were used, and the author describes in detail the data which he obtained from the analyses. It was found that the fuel represented mixtures of various hydrocarbons with boiling points from 69 to 120 deg. cent. (156.2 to 248. deg. Fahr.). He determined the upper heat limit of the gas by means of a Berthelot-Mahler bomb calorimeter and found that the

upper limit of benzole No. 1 was 9777 cal. per kg. (17598 B.t.u. per lb.) and benzole No. 2—9902 cal. per kg. (17823 B.t.u. per lb.). The article is not finished. Terres, *Journal für Gasbeleuchtung*, vol. 57, nos. 39 and 40, pp. 893 and 907, September 26 and October 3, 1914, serial article, not finished. *et. l.*)

Mechanics

FLOW OF OIL FUEL IN PIPES

Data on frictional resistance to flow at varying temperatures of four kinds of oil fuel in pipes of three, four, and five in. diameter.

It is taken from a report of the National Physical Laboratory through *Page's Engineering Weekly*. For the purpose of these tests, special appliances were constructed and include a centrifugal pump with adjustable speed regulation for producing the flow, weighing tanks for measuring the flow, circulating pump and coils for heating and cooling the oil to the required temperatures, and sensitive gages for measuring the fall of pressure along the pipe. In considering the method to be adopted for producing and maintaining a steady rate of flow through the pipes, it was realized that the frictional resistances to be measured were so small that the use of a plunger pump connected directly to the pipes was precluded on account of the fluctuation of pressure that would be produced. Flow under gravity from a large supply tank erected at a height above the laboratory floor sufficient to give the maximum flow required would have been the most satisfactory method, but as the expense of installing this arrangement would have been considerable, it was decided to design a special form of centrifugal pump for effecting the circulation. This was found to work quite satisfactorily, with the exception that in the case of the thickest oil tested, which had a viscosity at 15 deg. cent., which is 3,000 times that of water, circulation could not be produced at temperatures below 22 deg. cent.

As, however, the flow was streamline in character for temperatures far above this value so that the resistance could be predicted from the known values of the coefficient of viscosity, the necessity for observations at low temperatures on this oil was not of great importance, and it was decided to make the low temperature experiments in pipes of small diameter at the conclusion of the research. The pipes used for the experiments were cold drawn steel and about 140 ft. in length. The fall of pressure was taken on a length of 5 ft. situated about 45 ft. from the outlet of the pump, and was measured by a sensitive mercury tilting gage. In this way a pressure of 0.005 in. of water could be detected. (*Page's Engineering Weekly*, vol. 25, no. 530, p. 459, November 6, 1914.)

UNIFORMITY OF RUNNING OF PRIME MOVERS AND ITS EXPERIMENTAL DETERMINATION.

Discussion of causes of lack of uniformity in the speed of rotation of prime movers; methods of its experimental determination, and description of apparatus designed for this purpose by the author.

In a paper presented to the Aix-la-Chapelle section of the Verein deutscher Ingenieure, Doctor Bonin, after indicating various causes for the lack of uniformity in the speed of rotation of prime movers, especially machinery driving ships

and electric lighting generators, indicated that the construction of experimental devices for determining the uniformity of such machinery is an extremely difficult problem. A pendulum tachograph for the investigation of governing processes did not give sufficiently reliable indications as to the variations of speed during a single revolution, because the pendulum of the indicator itself might get into oscillations which affected the equilibrium of the pendulum. Riehm, in 1912, succeeded in practically limiting these natural oscillations of the pendulum by resorting to the use of an electric eddy current tachometer with an extremely small oscillating mass. Since, however, in order to maintain the oscillating mass as small as it was, he had to use a beam of light as a recording medium and make the record on a photographic plate. The apparatus is not suitable for shop use.

Tests of Mader, who attempted to determine the motion of the engine from single harmonic oscillations by means of an apparatus which he called "undograph," and also the exact law of motion of the engine from the data thus obtained, have been successful in their way, but again the process is far too complicated to be used commercially. Attempts have been made also to record the motion of an engine as a function of time, but when the small scale which can alone be used for practical purposes is employed, the deviations of the curve so obtained from the ideal straight line are so small that no reliable data as to the uniformity of motion of the engine can be secured therefrom.

In the apparatus designed by the author, the pendular paths are recorded directly. A freely rotatable and exactly balanced fly-wheel mass coupled with the engine by a moveable pawl so that it will have the same speed of rotation as the engine and also the same variations of speed is placed on a prolongation of the engine shaft. Should this mass be suddenly freed from its connection with the engine, it will run at the same speed which the engine had at the instant of uncoupling, and further, the speed of rotation of the mass will remain nearly exactly the same while the engine in its rotation will sometimes lead and at other times lag behind the mass. These motions may be recorded on a drum running at uniform speed by means of a light recording pen located between the mass and the engine, the record being such that the abscissae are times and ordinates are the relative paths of the engine with respect to the mass. From this oscillation diagram by some process of differentiation, the relative velocity of the engine with respect to the mass can be determined for each instant, and by this means also the degree of non-uniformity. The oscillation curve in the apparatus proposed is recorded by means of a steel scriber on a specially prepared sheet in such sharp lines that it can be read with great precision. The speaker found it to be so during his tests on a calibrated device and on a gas engine. (*Über die Gleichförmigkeit des Ganges von Kraftmaschinen und ihre experimentelle Bestimmung*, paper by Dr.-Ing. Bonin before the Aix-la-Chapelle section of the Verein deutscher Ingenieure read on June 17, 1914, published in *Zeits. des Vereines deutscher Ingenieure*, vol. 58, no. 46, p. 1562, November 14, 1914, 1 p. *et. l.*)

THE PRINCIPLE OF SAINT-VENANT AND THE SOLUTION OF PROBLEMS ON BEAMS.

Application of the Saint Venant principle to the solution of problems on beams.

The abstract is translated from *Beiblätter zu den Annalen der Physik*, as the original publication where the article appeared is not available at the present time. The validity of the principle has not been proved analytically except for particular cases. The author proves it for plain deformations in a beam. The analysis refers to a deformation of a rectangle acted upon on the narrow side by a system of forces of disappearing moment and disappearing resultant (in the plane of the rectangle), while the other three sides of the rectangle are free from stresses. It was found that the stresses in the rectangle, from the initial value, which they have in each of the narrow sides, diminish toward the interior of the rectangle very rapidly and nearly uniformly in accordance with the linear law and at a distance from the narrow side no greater than its own length hardly differ from zero. This holds even in the case where the length of the rectangle is about three times its width. (*Beiblätter zu den Annalen der Physik*, vol. 38, no. 21, p. 1297, and *Wiener Berichte*, vol. 123, pp. 33-51, 1914.)

FIG. 3. REINFORCED CONCRETE BEAMS IN TORSION.

blätter zu den Annalen der Physik, vol. 38, no. 21, p. 1297, and *Wiener Berichte*, vol. 123, pp. 33-51, 1914.)

PRINCIPLE OF VARIATION IN THE THEORY OF ELASTICITY.

The article discusses the application of the principle of variation in the theory of elasticity and its extension to the field of technical statics. It establishes two principles of variation. They are especially applicable to the treatment of lateral flexure of straight bars and bending of straight or curved bars.

If the principle of virtual displacements be applied to elastic bodies and only changes of shape be considered variable, it may be expressed in the following form:

$$\delta_1 [A - \sum Pw] = 0$$

where A is the work of change of form, or elastic potential, P the external acting forces, w their displacement along their direction lines, and δ_1 the variation in the change of shape. The author calls this equation the first principle of variation, and sets side by side with it, the second principle of variation which is derived from the principle of virtual dis-

placement, by considering only the forces as variables. It is

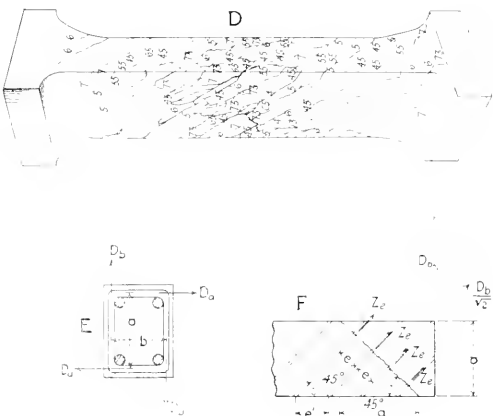

$$\delta_2 [B - \sum Pw] = 0$$

where B (in accordance with the notation of Engesser), is the supplementary work or work of potential, and δ_2 indicates that the variation refers only to the forces. (*Beiblätter zu den Annalen der Physik*, vol. 38, no. 21, p. 1298, and *Zeits. für Mathematik und Physik*, vol. 63, pp. 174-192, 1914.)

TORSION STRENGTH OF REINFORCED CONCRETE BEAMS.

The article discusses the torsion strength of reinforced concrete beams and shows experimentally how cracks develop when beams are subjected to torsional stresses.

The stressing of reinforced concrete parts in torsion does not occur frequently, but may occur when a beam is stressed normally to the plane of bending. The calculation of torsional stresses even in homogeneous and isotropic

materials of construction is only imperfectly possible and then only for rectangular cross-sections. It is natural, therefore, to expect that an exact calculation of stresses in the case of compound bodies would be still more difficult. It is possible to consider the reinforced concrete beams stressed in torsion as divided into two parts, one of which is stressed in bending exclusively (Fig. 3 A). Instead of the moment of torsion $M = Ph$ we may write

$$Q \cdot \frac{1}{3}h,$$

so that

$$Q \cdot \frac{3}{2}P = \frac{3M}{2h}$$

The two parts of the beam may then be considered as stressed in opposite directions by the loads Q ; the beams would have to be reinforced by steel as shown in Fig. 13. This method of calculation would have nothing objectionable in it if the beams were actually divided into two parts before the rupture of these parts and were then stressed in bending. As a matter of fact, however, the rupture of a prism stressed torsionally is entirely different, as shown in

Fig. D, which represents an actual case. This figure shows that the line of rupture on the faces of the prism run in inclined direction and this in its turn indicates that there are forces acting in torsion normally to these inclined lines, the rise of which can be explained in the following manner: In Fig. C is shown a prism stressed in torsion by two equal and oppositely directed couples. Owing to the change of shape, the original square $abcd$ on one of the faces of the prism, is distorted into the rhombus $efcd$, while the diagonal of the square db is elongated into the rhombus diagonal df . If now the ductility of the material is exceeded, an inclined fissure will be formed normally to the diagonal df . In test pieces made of isotropic materials, the formation of fissures can be observed only imperfectly as the conditions of formation of the first fissures bring about a total exhaustion of the strength of the material, and produce rupture. The line of rupture, however, does not always coincide with the line of the fissures as by the appearance of the first fissure, a body of somewhat different dimensions is formed in which the line of rupture has a different location from that of the fissures in the original body. Tests with reinforced concrete prisms were the first to show clearly the processes of formation of fissures through torsion, as in that case the load up to point of rupture could be still considerably increased after the first fissures have appeared.

Fig. D shows clearly the fissures which have been brought about by torsion on the reinforced concrete prism of rectangular cross-section. The prism had six reinforced bars 18 mm. (0.708 in.) in diameter and eight spirals 7 mm. (0.275 in.). Its dimensions are shown in detail in the original article, which contains also another photograph showing the fissures in a prism under torsion making an angle of 45 deg. with the axis of the prism. Tests thus show clearly that on all the faces of a prism in torsion there occur fissures inclined 45 deg. to the axis and that the spirals running normally to these fissures are stressed in torsion. Usually before rupture, the fissures are shifted from the external faces of the prism into the interior in such a manner that tensions which produce these inclined fissures have to be taken up entirely by the inclined steel elements of the spirals. Generally the tensions are uniformly distributed among these steel elements, but as soon as any section of the reinforced elements' limits of elongation has been reached, the tensions begin to be distributed nearly uniformly in the planes of the spiral. For this state of tension, it is possible to calculate the tension in the reinforced elements.

The author proceeds to consider a prism of rectangular cross-section, the sides between the center lines of the spirals being a, b , Fig. E. The moment of torsion is M and it may be considered as if consisting of two couples, each of the forces of these couples acting in a plane of the spiral.

$$M = D_a a + D_b b, \dots \dots \dots [1]$$

This moment when the limit of elongation of the spiral has been reached produces equal tensions Z , normal to the direction of the fissures when inclined at 45 deg., Fig. F. The forces D_a and D_b have, each, in the plane of the spirals components $\frac{D_a}{\sqrt{2}}$ or $\frac{D_b}{\sqrt{2}}$ which act in the direction of the spiral elements. If there are in the a plane ν reinforcing elements and in the b plane ν reinforcing elements affected by the fissures inclined at 45 deg., then the forces D_a and D_b ,

acting from the outside, are in equilibrium with the external tensile strength strain Z_e if

$$\frac{D_a}{\sqrt{2}} = \nu Z_e; \quad \frac{D_b}{\sqrt{2}} = \nu Z_e, \dots \dots \dots [2]$$

hence

$$D_b : D_a = \mu : \nu = a : b; \quad D_b = \frac{a}{b} D_a, \dots \dots \dots [3]$$

and from [1] it follows that:

$$D_a = \frac{M}{2a}, \quad D_b = \frac{M}{2b}, \dots \dots \dots [4]$$

Let us assume that the prism is equipped with k parallel spirals located at equal distances from one another. In a single winding, the spiral has the rise of $2(a + b)$, so that the spirals when measured in the direction of the edge of the prism have, from one another, a distance e' equal to

$$e' = \frac{2(a+b)}{k}, \dots \dots \dots [5]$$

and the minimum distance e equal to

$$e = \frac{e'}{\sqrt{2}} = \frac{\sqrt{2}(a+b)}{k}, \dots \dots \dots [6]$$

The lengths of the fissures inclined to one another to 45 deg. are

$$a' = a\sqrt{2}, \quad b' = b\sqrt{2}$$

so that the number of the reinforcing elements affected by the fissures is

$$\nu = \frac{a'}{e} = \frac{k a}{a+b}, \quad \mu = \frac{b'}{e} = \frac{k b}{a+b}, \dots \dots \dots [7]$$

By using these values in equations [7], [4], and [2], the

FIG. 4 SURFACE COOLER TUBES

author obtains the stress in the cross-section F_e of the spiral iron

$$\sigma_e = \frac{M(a+b)}{2\sqrt{2} F_e k a b}, \dots \dots \dots [8]$$

which in its turn permits the determining of the number of the spirals k .

Refrigeration

IMPROVED SURFACE COOLER.

Description of recent advances of German milking machine design, and among other things, of several types of milk and butter coolers.

The abstract contains a description of such a cooler. It is of the surface cooling type (Fig. 4), and consists of seamless drawn, copper pipes, thickly galvanized, located one over another to a height of 2.5 m. (8.1 ft.) for large coolers. The water flows in countercurrent to the milk. In order to produce further a still better exchange of heat and in this way save cooling water and especially space, a special round pipe was selected of the peculiar shape shown in the figure, which, within a small space, very materially increased the surface washed by the water. With a pipe so shaped, however, the automatic flow of water would not be as favorable as in the case of round pipes and in order to help

that out, at equal distances all along the pipe, very simple water-displacers have been located, as shown in the figure; this is claimed to assist materially the uniformity of the cooling action and thereby the better utilization of the cooling of the water. (*Die Fortschritte auf dem Gebiete der deutschen Molkereimaschinentechnik*, Ernst Kohl, *Dinglers polytechnisches Journal*, no. 42-43, p. 617, serial article, d.)

Miscellanea

THE DRYING OF SLUDGE AND ITS FURTHER USE.

The article describes an apparatus, based on the principle of centrifugal separation, for drying sludge.

It is designed by Hanoversche Maschinenbau. Akt. Ges. vorm. Georg Egestorf in Hanover-Linden, Germany, and the

several sections of the apparatus. The mud enters through the centrally located admission pipe *a* from a mud tank placed over the apparatus. Thence it goes into the centrifugal drum *b*, provided with several chambers equipped with screens *c* and inside and outside valves. It is there distributed through the separate chambers when the valve is opened. Through the action of the centrifugal force, the heavier particles of the mud are thrown into the external part of the chamber, while the specifically lighter water is forced out of the mud and flows out through the screens of the chambers into laterally located pipes, whence it is allowed to escape. The space which was formerly taken up by the water is then filled with a new supply of mud so that in a short time, the chambers are filled with mud practically free from water and air dried. Then the inner valve is opened,

FIG. 5. CENTRIFUGAL SLUDGE DRYER

engineers of the city of Frankfurt-am-Main. It has been known for a long time that by centrifugation, the sediment can be reduced to from 4/5 to 6/7 of its original volume, and this fact was placed as the basis of design in the new apparatus to take care of the very large amount of sediment in the Frankfurt plant. In Germany, the amount of sewage waters in the cities varies from 100 to 200 l. (26.4 to 52.8 gal.) per day per unit of population in places where no particular causes for its increase are present, but rises to from 300 to 400 l. (79.2 to 105.6 gal.) per day per unit of population where there are extensive dye or laundry works. The sewage has been found to contain from 5 to 10 per cent of solid matter, and from 95 to 90 per cent of water.

The working process in the centrifugal separator is divided into two periods. In the first period, the sediment entering into the apparatus is dried by centrifugal separation of the water; in the second period, the solid particles remaining in the machine are eliminated. Fig. 5 A, B, C give

a further inflow of raw mud is admitted and the dry mass in the chambers is separated from the wet mud in the admission pipes. The external valve is then opened and the dry stuff is allowed to escape from the apparatus. Owing to the action of centrifugal force, the mass is violently thrown against the walls of the casing and thereby broken up into small particles. It is taken care of later by a conveying device located under the apparatus.

The violent action of throwing the mud against the screens tends to keep them fairly clean. In order, however, to insure more fully their cleanness, and in this way to prevent the stoppage of the flow of water, the screens are provided with a special mechanical cleaning device, viz., star shaped brushes which are given a reciprocating motion by a special drive. When the chambers are emptied, the outer valve is closed, the inner one opened and the process repeated. The valves are driven by oil under pressure which is admitted from below through a bore in the vertical shaft *f*. The admission of the oil under

pressure into the cylinder of the control valve is regulated by a rotating disc. The drum is enclosed in a strongly built casing and is driven by a belt. The parts of the casing which are subject to the action of centrifugally thrown masses are made of wrought iron. The drum shaft has three bearings, and in this way the weight of the drum is equalized through the oil under pressure admitted for operating the steering gear.

Around the centrifugal drum is located a concentric ring which takes up automatically the water escaping from the drum, and removes it shortly before the exit of the dry mass. After the dry matter has been taken care of, the ring returns automatically into its original position. This arrangement prevents the particles of water from staying on the periphery of the casing and mixing up again with the dry material thrown out by centrifugal force. In view of the great pressure exerted by the centrifugal force in the drum, it is impossible to prevent the appearance of water on the periphery of the casing even with the best packing of the valves, but the ring device described makes this water entirely harmless. The power consumption of this centrifugal separator is about 12 h.p. In order that the apparatus shall work without trouble, all large and hard pieces are removed previous to the entrance of the mud into the separator. This is easily done by passing it through a grating with slots 8 mm. (0.314 in.) wide.

The mass obtained from the apparatus can be used either for agricultural purposes or as filling material, and recently attempts were made to burn it in incinerators by gasifying it with some addition of coal. The tests of gasification and burning of the dried sewage sediment have been made at the Frankfort plant. The mud had been dried in the centrifugal apparatus to the extent of removing from 30 to 40 per cent of its water content. Then it was dried in drying drums by the use of blue gases down to 20 or 25 per cent of its water content, and in this state was added to the material fed to the incinerators in the ratio of one to ten. It was found that such an addition raised the output of electrical energy from 65 to 80 kva per 100 kg. (220 lb.) of mixture, which means an output of 150 kva per 100 kg. of mud. When the mud with 20 to 25 per cent water content is gasified, an average of 25 cu (per ? — not stated) of pure gas, with an average heat content of 4000 WE. at 448 B.t.u. per cu. ft. is obtained and, in addition, a valuable by-product secured, from 50 to 60 per cent of nitrogen contained in the sediment being converted into ammonia. The economy of the plant is still further increased through the utilization of the coke produced during gasification, which possesses a heating value of approximately 1200 WE. (2160 B.t.u. per lb.).

The article also contains data on the handling of the mud in municipal gas works of the cities of Brünn and Hannover. (*Tricknung von Klarschlamm und seine Verwendung*, Hubert Hermanns, *Zeits. für Dampfkessel und Maschinenbetrieb*, vol. 37, no. 44, p. 485, October 30, 1914, d.)

Multiple Effect Compression as Applied to CO Refrigerating Machines, H. Brier

Cooling of the Liquid CO in Refrigerating Machines, F. A. Wilcox and G. C. Hodsdon
EXCESSIVELY DRY AIR IN COLD STORES, WM. D. SAWERS (abstracted)
EXCESSIVELY DRY AIR IN COLD STORES, WM. D. SAWERS (20 pp., p.).

The author discusses the action of excessively dry air in cold stores on the goods stored therein and the various ways of mitigating and regulating such action.

The favored system of air cooling in cold stores is the so-called wet brine method in which the circulating air is cooled by direct contact with refrigerating calcium chloride brine. This method, which has its advantages, produces, however, a dryness of air due to the powerful desiccating action of calcium chloride at low temperature. It appears that as the temperature of the solution goes down, the desiccating properties increase to an enormous extent and comparatively weak solutions of the salt which at normal temperatures would evaporate, take in moisture in a rapidly increasing degree as the temperature becomes lower.

The author made a number of careful tests of the relative moisture-absorbing properties of different strengths of calcium chloride solutions at different temperatures. The solutions were left exposed to the air in rooms maintained at temperatures of 60, 35 and 17 deg. Fahr. and the loss and gain in weight due to evaporation or absorption of water noted at intervals. Ordinary fused calcium chloride was used for making the solution and three different strengths were made, approximately 20, 25 and 30 per cent. solutions, the other conditions of the test being kept as far as possible identical. At 60 deg. Fahr., the brine loses moisture in a lessening degree as the strength of the solution used is stronger. With 30 per cent. solution, the action comes to a standstill and it neither loses nor gains water. At 35 deg. Fahr., 20 per cent brine gives up water fairly rapidly and 25 per cent brine neither gains nor loses weight, while 30 per cent brine absorbs moisture from the air rapidly. At 16 deg. Fahr., 20 per cent brine slowly absorbs, 25 per cent rapidly and 30 per cent takes in moisture with great avidity.

It is evident, therefore, that the drying action of calcium brine becomes very much intensified if too strong a brine is used, consequently the making up of brine in a cold store is a detail that requires more attention than it usually receives, the general tendency being to keep the brine unnecessarily strong, which is due principally to a dread of the solution freezing on the ammonia coils. On the contrary, the brine should be maintained so far as possible at a constant minimum density by putting in the calcium chloride frequently and in small measured quantities. With constantly moving brine at a temperature of, say, six to nine degrees Fahr., the density can be quite safely kept well below 1.155 sp. gr. (17½ per cent) at 60 deg. Fahr. The author found that actual practice of this procedure effected a decrease in consumption of calcium chloride: for a space of 90,000 cu. ft., over three tons less chloride were used on a year's run as compared with previous working, while the appearance of certain classes of goods coming out of storage is distinctly improved.

The best way to obviate this difficulty would be to find some other chemical which would serve as a suitable substitute for calcium chloride in the brine, but which would be free from the drying action. Magnesium chloride also possesses strong drying properties. Common salt absorbs

moisture to a very slight degree, but its solution does not remain liquid at low temperatures. The author tested a brine made of mixed calcium chloride and common salt, but found that curiously enough, the calcium chloride seemed to convey its properties to the common salt and the solution was as active a dryer as if it had been made with calcium chloride alone and had the same density. He suggests, therefore, the use of a cooler in which the air passes over dry metal surfaces, so constructed that the snow, as it forms, may be continuously and automatically scraped and brushed off, but he does not describe its mechanical design.

ENGINEERING SOCIETY OF CHINA

REPORT ON CHINESE CONCRETE.

The article gives a copy of a report made to the Engineering Society of China by a special committee which that Society appointed to investigate the question of reinforced concrete, such as preparation, strength, properties and use in engineering and building work, with special reference to local conditions in China. The article gives data on the materials used in the manufacture of concrete in China as well as the method of carrying out tests.

FIG. 6. COUNTER-CURRENT IN ECONOMIZERS

As the original publications of the Society of China are not available at the present time, the abstract is based on a reprint in *The Engineer* (London). The data of Table IV have been obtained. The results are by no means regular and the general superiority of the beams made with Pingchiao stone has been found in some cases. The difference between steel and iron is greatly in favor of the former. A consistent advantage was also found in favor of beams with hooked reinforcing bars as compared with beams with plain steel bars. In the case of iron bars, in some cases it was found that beams with hooked bars failed at a lower pressure than beams with straight bars. The first cracking invariably took place where the deflection was between $\frac{1}{16}$ and $\frac{3}{32}$ inches. At first, the cracks appeared distributed over the whole length of the beams at a distance of six to eight inches apart. With the increase of the load, the cracks nearest the center became larger, but when the maximum load was reached, with a deflection of $\frac{5}{16}$ to $\frac{3}{8}$ inches, a very dis-

tinct difference was visible between the beams reinforced with steel and those reinforced with wrought iron.

All beams reinforced with indented steel bars showed at the maximum load several wide cracks near the center tending to join each other at the top below the center where the load was applied. All other cracks further distant from the center had disappeared by then. Only three beams failed by the destruction of the bond between the steel and the concrete. All beams reinforced with wrought iron bars showed one large crack near the center, while all the other cracks had closed. In regard to slabs, those reinforced with steel failed more suddenly than those reinforced with iron.

Concrete was found to be less fire-resisting the greener and richer it was. None of the local materials can be considered as very fire-resisting in connection with concrete. Pingchiao stone, and especially gravel, have a tendency to destroy the concrete on account of their comparatively greater expan-

tion. The report contains also data regarding the permeability of Chinese concrete and the effect of electrolysis. (*The Engineer* [London], vol. 118, no. 3072, November 13, 1914, p. 456.)

Journal, vol. 6, no. 8, August 1911, Harrisburg, Pa.

The Monessen Viaduct, Thomas Fleming
The Counter-Current Principle as Applied to Directly-fired and to Waste-heat Boilers, George H. Gibson (abstracted)

THE COUNTER-CURRENT PRINCIPLE AS APPLIED TO DIRECTLY-FIRED AND TO WASTE-HEAT BOILERS, George H. Gibson.

The author discusses the use of economizers with directly-fired and waste-heat boilers and comes to the following important conclusion: *First*, that with directly-fired boilers, contrary to the usual assumption that economizers begin to be profitable only when the price of coal reaches \$2.00 per ton and the load factor exceeds 50 per

cent, actually, economizers can be used profitably regardless of the fuel price and of the load factor. *Second*, in the case of waste-heat boilers, such boilers and turbines should be put in for as high steam pressures as are practical in view of other considerations, and the boiler should be supplemented by an economizer in order to obtain the greatest amount of power and at the lowest cost from a given amount of gases.

The author reaches these conclusions in the following manner: He begins by establishing the margin of diminishing returns as applied to waste-heat and directly-fired boilers. In the first case, the principle of diminishing returns expresses itself by the fact that there comes an economical limit to the recovery of waste heat beyond which it does not pay for the increased investment. In directly-fired boilers, after the gases have been cooled to a certain temperature, the heating surface required to cool them further does not produce steam as cheaply as it can be produced by the heating surface, including the cost of fuel, preceding that point. Thus, if the gases are to leave the boiler at 200 deg. above the steam temperature, there will be generated approximately $4\frac{1}{2}$ lb. of steam per hour per square foot of surface, and about 6.5 sq. ft. of surface will be required to produce a boiler horse-power of 30 lb. of steam per hour. With steam at 366 deg. Fahr., the flue gases will be at 566 deg. and will still contain a large proportion of the total heat of the fuel. Assuming that 24 lb. of air have been used to burn one pound of combustibles, the loss will amount to approximately 25 per cent, and after allowing for radiation and other losses, the boiler efficiency will be less than 70 per cent.

To recover this heat by means of heating surface and steam temperature is not profitable, but it may be so done by giving up the heat to the boiler feed water in the economizer where, assuming that the economizer's heating surface will have the same coefficient of transmission and the same fixed charges as the boiler surface, we should theoretically be able to reduce the temperature of the flue gases in the above case to within 200 deg. of the initial water temperature, i. e., to 300 deg., with a saving of approximately 13 per cent of fuel (actually somewhat more, because the economizer surface costs less per square foot to install and requires less attention).

The author discusses in an interesting manner the rate of heat transmission in the case of the economizer, as well as the question of the coefficient of heat absorption by convection or contact. If cooled to within 200 deg. of the steam temperature, the gases from a directly fired boiler will not be sufficient generally to raise the boiler feed water to near boiling point, but as the water in the economizer is lower in temperature than the water in the boiler, the economizer surface is more active and hence more profitable than boiler surface up to the point when the water reaches the boiler temperature. It would pay, therefore, to reduce the amount of boiler surface per h.p. developed to less than 6 $\frac{1}{2}$ sq. ft. per h.p. required to cool the gases to within 200 deg. of boiler temperature. The author gives as an example a description of a 1000 h.p. boiler, superheater, economizer and mechanical draft unit, laid out according to proportions determined in his discussion, and shows how this installation confirms his views that if an economizer is not installed, the boiler must accomplish the same office in heating the water up to evaporation point, but will do it with a lower efficiency because the boiler also contains water at the steam tempera-

ture while the economizer utilizes the lower initial temperature of the water to increase the heat absorption.

In the waste heat boiler, if the steam temperature is near the initial gas temperature, the boiler must be large because of the small temperature difference available for transmission or inefficient because it must allow the gases to escape while still at high temperature. At the same time, the efficiency of the turbine or other engine will be good because of the high initial temperature and pressure. If the steam temperature be gradually reduced, the efficiency of the turbine will be poor, while the boiler required will be smaller and its efficiency high. Therefore, two solutions appear to be possible, viz., to have the boiler operate at a moderate pressure or to have a small boiler operate at a high pressure and another boiler and economizer at a lower pressure in connection with a mixed flow turbine receiving high pressure steam from a high pressure boiler and low pressure steam from a low pressure boiler.

It appears, however, that the commercially best and most practical solution is a high pressure boiler in combination with an economizer and a high pressure condensing turbine. For instance, at 366 deg. Fahr., corresponding to 150 lb. gage pressure, about 12 lb. of steam are required per turbine h.p. (a turbine 65 per cent. Rankine efficiency, saturated steam exhausting to a 28 in. vacuum referred to a 30 in. barometer) at 212 deg. approximately 24 lb. of steam are required, but at atmospheric pressure the steam is worth only one-half as much per pound as steam 150 lb. gage, which determines to what extent it will pay to reduce the temperature of the gases by means of boiler surface. From Fig. 6, the curve marked "Temperature gases leaving boiler," it is seen that in any case it will not pay to reduce the temperature of the gases in the boiler below 500 deg. Fahr., at least in competition with directly fired boilers burning \$1.50 coal. By installing an economizer to supply the heat required to raise the feed water from 100 deg. Fahr. up to the evaporation temperature, the final temperature of the gases will be reduced as shown by the curve marked "Temperature of gases leaving the economizer." The higher the steam pressure carried, the lower the final gas temperature and hence the greater the capacity as well as the economy of the unit.

The most striking result, however, of using the economizer is the greater increase in horse-power obtainable from each 1000 lb. of gases as shown by the curve marked "Horse-power per 1000 lb. of gas from boiler and economizer," the increase at ordinary steam pressures being about one-third. To determine, also, the variation in the cost of power produced by using the economizer, it is necessary to fix the annual costs of the two kinds of apparatus (Fig. B). For the boiler \$2.00 per square foot has been assumed as the cost installed, including settings, flues and fittings, with an annual charge including repairs, depreciation and attendance taken at 17 per cent. For the economizer, the cost per square foot installed has been put at \$1.50 and the annual charges at 15 per cent. A high pressure turbine has been assumed to cost \$10.00 per h.p., installed complete with condensers and auxiliaries and the turbine receiving steam at atmospheric pressure, \$20.00 per h.p. From the curves of total cost, including the steam cost, it will be seen that if the plant is operated with saturated steam at the initial temperature of 400 deg. Fahr., the annual cost per h.p. is \$4.10. The same with the turbine receiving steam from a directly

fired boiler using coal at \$1.50 per ton would cost a little over \$10.00 per year. From Fig. B it might appear, however, that when using the economizer, power costs more than when using the boiler only, but there the boiler is terminated at the point where it ceases to be able to compete with the directly fired boiler with \$1.50 coal. From there on, the gases are allowed to pass through an economizer in which they give a better return, until they can reach the same limit.

In a plant where the waste gases would produce a surplus of power, it might not be advisable or necessary to add the economizer, but as soon as the need of burning fuel under boilers to produce steam for power appears, it will pay to add the economizer both because of the greater amount of power thus obtainable from a given amount of waste gases and because the power so obtained is secured more cheaply than it would be secured from a directly fired boiler.

Proceedings, vol. 30, no. 6, July 1911, Pittsburg.

TEST OF LARGE REVERSING ENGINE AND ROLLING MILL, Karl Ni Becker (107 pp, 56' figs. *cd.1*).

The article describes a twin tandem compound reversing

FIG. 7 VALVE GEAR OF REVERSING ROLLING MILL ENGINE

engine driving a 44 in. reversing bloom mill when rolling 20 x 22 in. ingots, as well as the methods used in testing that engine and assumptions made in determining the power and steam consumption for this mill. Further, it considers the steam consumption per unit of metal deformed and the power losses involved in this operation.

The engine is operated condensing, using steam at 140 lb. gage pressure at the throttle valve and exhausting into a 28 in. vacuum. It is direct connected to the mill, but separated from it by means of a brick wall. Fig. 7 represents a diagrammatic arrangement of one side of the engine and valve gear, showing the method of control. It has been previously used in Europe, but is rather new in this country. The mechanism is operated by a single lever shown at 1. This lever, located in a pulpit, operates the relay valve which controls the steam to the reversing cylinder operating both the reversing links and the throttle. The reversing piston is cushioned by means of a suitable oil cylinder connected to the reversing gear crosshead.

The three positions of the main reversing lever crosshead

are shown by points 1, 2 and 3, the pressure of the steam through the throttle valve and the point of cut off being both determined by the motion of this cross-head, and it is essential therefore that the engine when operating under light loads, should work with the combination of throttle and cut-off control. The throttle valve is so arranged that its opening does not occur with the beginning of the movement of the reversing lever from its center position. A certain amount of lap is provided so that the valve gear is moved an appreciable amount from its neutral position before the steam valve is opened. When the throttle valve opens, the steam is admitted from auxiliary ports in the main piston valve. By this combination of lap on the throttle valve and auxiliary ports in the main valve of the engine, it is possible to start the engine at any position of the cranks. The auxiliary ports are in operation during the regular running of the engine but are too small to affect the economy of the engine or the shape of the indicator cards.

Continuous indicators were applied to each end of the four cylinders, equipped with electro-magnets for starting and stopping the paper and also for applying the pencil to the drums. The other four indicators were manually started and stopped at a given signal operated by the same key which actuated the starting magnets on the electrically operated indicators and were supplied with electro-magnets for locating the various events. The point of opening and closing of the steam throttle valve was recorded by means of one magnet. The position of the cross-head of the reversing cylinder was determined by a magnet on one of the indicators which indicated when the piston of the reversing cylinder was in its dead center position and when it was off the dead center position. The dead center position of this piston represented the point where the steam throttle valve was closed and the links were in their neutral position. On one indicator, a magnet was provided for recording one-half second intervals, thus giving a record of time. A figure in the original article is given to show the electrical connections but unfortunately it is too blurred to permit reproduction here. Storage batteries were used for furnishing the current for operating the instruments, and temperatures were read by means of a Wanner optical pyrometer. A three point recording thermometer was installed on the condenser and also a vacuum gage carefully calibrated by means of a mercury column.

The author describes in detail the methods used in working up the indicator cards which are those described by Siebert and Fitzgerald in the *Proceedings of the Engineers' Society of Western Pennsylvania*, volume 29, No. 8. It was found that 34.5 per cent of the total available work is consumed in accelerating and retarding the rotating and reciprocating parts, 9.8 per cent in friction and only 55.7 per cent is actually consumed in deformation of steel. The amount consumed by the engine in accelerating and retarding the parts is in this case inordinately large as tests on other engines have shown that this value can be as high as 15 per cent only and even lower. The engine in question, however, runs without the slightest vibration and has shown no wear on boxes, pins or bearings. While smooth running is a desirable feature, it does not always pay to spend too much in steam consumption to obtain it. On the other hand, the amount of power consumed in friction, 9.8 per cent, is exceptionally low and has been obtained by large short bear-

ings properly lubricated and by perfect alignment. The couplings used are of a special design and machined to eliminate all lost motion and reduce friction. Cut pinions are also used. The average value of the steam consumed per i.h.p. hour is only about 21 lb., which is exceptionally good.

This engine disproves the statement sometimes made that it is impossible to produce a high vacuum in the cylinders of a reversing engine since a vacuum of 25 in. in the low pressure cylinder has been here obtained with 28 in. in the body of the condenser. The author describes the low steam consumption of the engine to single lever control, and the consequent importance of using a large amount of steam for "plugging" the engine and throttling the steam for controlling the engine, as well as to well set valves giving high compression. At the same time, the engine has been found to reverse quickly: it requires approximately three-fifths of a second to move the lever through its entire travel and one and one-half seconds are required from the beginning of the movement of the reversing lever until the links are fully reversed. From one-half to one second is the time required for the links to reach their new extreme position after the lever has been thrown to its new extreme position.

The author calls attention to the excess of steam consumed per ton due to difficulty with manipulation of the piece and also to the piece not entering the rolls properly. With very little trouble, the steam consumption per ton can be increased 30 per cent, and it has been found also that one operator may use from 10 to 15 per cent more steam than another, although both may be considered expert engineers with a large amount of practice upon this mill. The author reproduces a table showing the increase which may be met with when rolling various sizes under different conditions of temperature and handling of the piece. In general, it appears that with a moderate amount of ordinary difficulty in manipulation and operation, the mill should consume less than 500 lb. of steam per ton of steel rolled constantly. A summary of the results as calculated by H. C. Siebert is given in Table 10:

TABLE 10. SUMMARY OF RESULTS

Set Number	7	15
Weight of Ingot—tons	2.74	2.46
Length of Ingot—ft. and in.	4 ft. 9 in.	4 ft. 2 in.
Average Area of Ingot—sq. in.	379	369
Section of Bloom—in.	47 x 6 1/4	7 x 5 1/8
Area of Bloom—sq. in.	32.9	35.9
Length of Bloom—ft. and in.	55 ft. 0 in.	47 ft. 0 in.
Elongations	11.52	11.10
Indicated Work—h.p. sec.	211,106	206,113
Friction Work—h.p. sec.	37,465	33,600
Acceleration Loss—h.p. sec.	61,901	77,014
Available for Rolling—h.p. sec.	111,740	95,499
Friction Work—per cent.	17.8	16.4
Acceleration Loss—percent	29.3	37.3
Available for Rolling—percent	52.9	46.3
Total Steam—lb.	1,392	1,272
Steam per ton—lb. (Elongations—lb.)	175	151
Steam per c. p. Hour (Dcs. from Ind. Cards)—lb.	17.1	17.1
Steam per c. p. Hour (30 per cent. for loss)—lb.	22.2	22.2
Temperature—deg. F.	2,245	2,200

In the discussion which followed, Charles Fitzgerald, Jr., took exception in regard to the test methods to the marking of one-half seconds points on the indicator paper for the purpose of plotting speed curves since the instantaneous linear speed of the paper is proportional neither to time nor to the speed of the engine. The curve plotted in this manner shows only approximately the general shape but is not

valuable as a means of applying a kinetic energy factor to the solution of the problem of actual force applied at the rolls. The location of the passes by this method is also open to error unless checked by the indications of a correct speed curve which shows plainly the period of the bloom in the rolls. The speaker thinks that 18 lb. per i.h.p. looks too good to be true.

FRANKLIN INSTITUTE

Journal, vol. 178, no. 6, December 1914, Philadelphia, Pa.

WING DATA AND ANALYSIS FOR A STAGGERED BIPLANE, A. F. Zahm (16 pp., 9 figs., p.)

The article presents data for a staggered biplane with the spars continuous from body to wing and the angle of incidence varying with the speed, thus causing the line of resultant lift to travel.

The article is too long to be fully abstracted here and only certain parts will be given. Fig. 8 shows that as the wing of incidence varies throughout its assumed range of 0.5 to 12 deg., the center of pressure moves fore or aft through about one-fourth the chord; thence, if the spars be placed

FIG. 8. SECTION OF WING. STRUT SHAPE. WIND FORCE ON WING PLANE

too near together, each spar in turn may have to sustain the whole load and the farther apart they are placed, the less the portion of the load varies. In the wing under consideration, the spars can be placed 48 in. apart and yet have sufficient depth within the canvas. The running loads have been graphically resolved in the plan of the plane of the front struts and of the top spars to obtain the running loads in these planes and hence the tensions and compressions borne by the truss members in the planes. Likewise, they have been resolved in the plan of the spar web in order to define the bending moment of the spar due to the net running load on it.

For the spacing of the struts along the spars the following method was used. The distances between the struts along the wing were so chosen as to make the bending moment in any spar the same as that of its joint joints. Thus the overhanging wing end is a uniformly rotating cantilever beam and has a bending moment next the strut of $\frac{17}{12}$ if

If be the known running load on the spar and l the length of the overhang. The next span is a uniformly loaded beam

with fixed ends and next to each strut, has the bending moment $\frac{Wl_1^2}{12}$, where l_1 is its length. The next span is a uniformly loaded beam fixed near to the strut and pinned at the engine section and next to the strut has the bending moment $\frac{Wl_2^2}{8}$, l_2 being its length. Since these three moments are to be equal

$$\frac{Wl_1^2}{2} = \frac{Wl_2^2}{12} = \frac{Wl_3^2}{8}$$

and since the sum of the span length equals the given wing length

$$l_1 + l_2 + l_3 = l$$

the equations can be solved for l_1 , l_2 and l_3 .

The article discusses in detail the graphical determination of the applied forces and reactions in the plane of struts and in the upper and lower planes as well as the assembled dimensions and computed values and proceeds then to the total analysis of stresses and loads.

NEW ENGLAND RAILWAY CLUB

November 10, 1911, Boston.

TYPICAL RAIL FAILURES, F. A. Weymouth (46 pp., 46 figs. *dp.*). The paper describes various causes of rail failures, gives a classification of defects, and discusses the so-called frictionless rail.

A logical classification of rail failures seems to be one that places them under headings descriptive of the manner in which the failure develops or occurs in service. The author considers rail failure under four main headings: first, crushing of the head; second, flowage of the top metal of the head; third, broken rails, and fourth, rails worn out from abrasion. Under the heading of *crushed head failures* are placed all rails that indicate a flattening of the head or breaking down of the head structure, *i. e.*, the under side of the rail head shows distortion. Many of the crushed-head rails are called also "split-head" when they show a splitting of the head; but this term is merely an amplification of the term crushed-head. Some rails are termed "pipel," which suggested that this type of failure comes from the presence in the rail of unvelled surfaces of the original cavity of the ingot. Naturally, however, only very few failures are traceable to this cause and it seems best to use the term "crushed-head" in all such cases.

Crushed-head rails in track are readily detected in three ways: first, a widening out of the head is very apparent in tracking; second, a dark streak appears in the center of the top of the head of the crushed portion, indicating that that portion of the metal is depressed and is not receiving the usual brightening from the wheels; and third, the distortion or breaking down of the head structure can be detected by a sufficient template or the appearance of a ferro streak in the head. The crushed head occurs partly because of the battering of the top surface of the metal due to low joints and also because of uneven tamping of the ties. It may occur in unsegregated rails as well. This has been shown by a special machine designed at the Maryland Steel Company for the purpose of reproducing the condition of the wheel loading that the rail gets in service.

The term "flow of metal" failure is used to describe rails that show a rolling-out or *flowage* of the top metal of the head toward the sides without a breaking down of the head

structure. It may occur in many different forms and be due to various causes, such as improperly maintained or poorly designed joints, a vertical movement of the rails and especially the effect of different types of supports. One of the most annoying types of flow metal is that which has been given the name "flow in spots," which causes what is sometimes called a "roaring" rail. These spots occur on the gage corner of the head. No satisfactory explanation of this type has been evolved, but intense localized wheel pressure which stretches the metal beyond its elastic limit is one of the causes mentioned. The effect of slipping drivers and all slipping wheels is also very marked in the development of rails that fail from flow of metal. While flowing metal itself is not dangerous, it may form a starting point for the development of splits, crushed heads and breakages.

The author proceeds to discuss failures from breakages such as flange breaks, breaks across the rail section, and breaks in the web. He discusses the claim that flange breaks are the result of lack of transverse ductility in the rail accompanied by the presence of seams and agrees with the view that a large number of flange breaks are due to the presence of seams which are elongations of small cracks formed in the ordinary process in rolling the ingot. As regards the action of slipping drivers, an investigation was made by placing in one of the tracks of the Maryland Steel Company a rail which was then shipped on by a light locomotive. The rail was then removed from the track and bent under the tensile machine. At the part where the rail was not slipped on, it stood a load of 200,000 lb. without fracture, while at the point where the drivers had slipped on the rail, it broke at 160,000 lb. pressure. Scleroscopic hardness tests made on that part of the section showed 80 hardness against 37 for the average for the rest of the metal in the head.

The name of transverse fissure is given to a fractured rail section that shows smooth track or silvery spots in the head, while the rest of the metal is granular. It is found on the fractured surface usually without any connection with the outside skin of the rail, indicating that it is an internal fissure that radiates from a nucleus. No satisfactory explanation of the cause has as yet been evolved.

As regards rail abrasion on straight track, normally only simple flowage is found due to the wheel pressure and the wearing away of the top fillet of the rail on the gage side to fit the nuts of the wheel flange or on curves; a number of different types of rail wear is found, each imposing a different set of strains upon the rail. The author proceeds to discuss the wear on the high rails, the influence of worn wheels on the shape of the rail (formation of false flange on the rim) and finally the use of the so-called frictionless rail.

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS

Advance copy of paper read at meeting on November 25, 1914, Newcastle-upon-Tyne.

THE REMARKABLE FAILURE OF A CONSIGNMENT OF STEEL SHIP PLATES, W. J. B. Wilson (11 pp., 11 figs. *dp.*). The paper describes an unusual failure of steel plates used in the construction of an ice breaker and the tests performed on these plates. It shows that such usual tests as chemical analysis, tension, bending, punching and forging tests, as prescribed by Lloyd's, are not always sufficient to determine the properties of the material, and steel which fully satis-

fies such tests may prove to be entirely unfit for service under these difficult conditions (winter service, etc.).

In 1907, the author's firm received an order for an ice-breaking cargo and passenger steamer to be built to Lloyd's highest class under special survey. The material for the shell had been tested and passed by Lloyds and characterized by the surveyor as excellent. In punching the garboard strake plates, several of them cracked, the failure having been put down to the severe cold prevailing (-13 to 18.4 degrees Fahr.). Later on a number of garboard plates cracked between the rivets, and some of them were so brittle that a single blow with an ordinary hand hammer knocked pieces out of the flange portion. The job of riveting the keel was at once stopped until a thorough hammer test of the flange portion of all the remaining garboard plates had been made. This proved perfectly satisfactory and the riveting was resumed. For some time practically no cracks occurred, then the cold again became very severe and several days later, one of the garboard plates which had been riveted in the ship was found to be badly cracked, the crack being clearly a case of spontaneous rupture. When this plate was cut out, the material in the way of the keel rivets cracked in the same way as the one described above and a new hammer test was made therefore with the startling result that every plate in the garboard plates cracked and in some cases, pieces fell out. A new survey was then made by Lloyds which proved satisfactory to the surveyor. The bend tests were excellent so long as the test pieces were not taken near any rivet holes. Chemical analysis for phosphorus was good, but still one blow of a heavy hammer was sufficient to knock large pieces out of the flange portion of the plate.

The article gives extracts from an official report of tests made, which indicated that the plates satisfied all usual requirements; after these tests have been made, the surveyors maintained that as the steel passed the test laid down in the rules, they were not justified in blaming the material unless a test could be devised which would, in their presence, prove the steel to be at fault. The author then devised a test carried out in the following manner: a butt strap which had not been worked into the vessel and a plate of material made in a Swedish steel works were placed in a mixture of ice and salt and the temperature of the plates reduced to -4 deg. Fahr. The plates were then quickly punched on one side for double riveting and riveted together, care being taken that the edges of the plate opposite the holes were kept cold with ice. After the plates were allowed to cool down, the rivets were driven out, during which operation the plate taken from the ship's material cracked badly and pieces dropped out. The plate from the Swedish steel works was also inspected but did not show any signs of cracks. These butt strap tests were sufficient to show that the material was really entirely spoiled by riveting, and that the Swedish material, although worked in the same way, gave no trouble at all.

The case of the plates was submitted to Prof. J. O. Arnold of the University of Sheffield, who made the following report. The chemical analysis was:

CHEMICAL ANALYSIS			
Percent		Percent	
CC.	0.05	S.	0.08
Gr.	trace	P.	0.06
Si.	0.08	As.	trace
Mn.	0.86		

The material is a dead-mild steel which, from a chemical point of view, is not of very good quality. A microscopic examination of the material showed the structure reproduced in the accompanying micrograph (Plate 1.). The very small carbon contents are centered into dark etching areas, best described as the fourth phase of pearlite, namely, when it is passing into ferrite and massive cementite. When such high sulphur as 0.08 per cent is present, dove grey areas of sulphide of manganese are scattered through the steel in very appreciable numbers. The crystals have sharp angular boundaries; indeed, the material appears to have been overheated in the manufacture, and gravely injured by the operation.

A number of alternating stress tests were made, giving extremely unsatisfactory results. The conditions of testing were the standard method adopted here, viz., the bars were 3½ in. diameter, and the distance from the zero of stress to the plane of maximum stress 3 in.; the deflection each way on the zero plane was 3½ in., and the rate of alternation 650 per min.

Good mild steel should endure a minimum of 300 alternations of stress. The faulty steel, however, in 8 tests averaged only about one-third of this, or 100 alternations. This is the worst steel of its class I have ever examined under alternating stress.

I have not had the tensile tests made, as in such cases these would be of very little use, usually giving very fair results. As regards the bends, I send also three of the bars used in the alternating stress tests. As you will see, they have bent double without any sign of a flaw. This also is quite usual.

I am a little puzzled as to the origin of this steel, since the high silicon, 0.08 per cent, suggests an acid steel. It may, however, be a basic steel, overheated with ore, to which manganese and silicon have been added in the ladle. If the carbon were, say, 0.2 per cent instead of 0.05 per cent, I should with some confidence class it as Bessemer steel; as it is, I find it difficult to suggest its method of manufacture with any degree of certainty.

The overheating to which I referred would take place in manufacturing the plates from the slab ingots. When such ingots are heated to too high an initial temperature and rolled, they leave the rolls at too high a temperature, cool too slowly and crystallize, and if such plates are stacked in heaps to cool, it is obvious that the cooling is still slower, and the crystallization more perfect, and hence more dangerous. . . .

This shows that the ordinary methods of testing, such as adopted by Lloyd's, are not sufficient to detect certain kinds of weaknesses in the materials; this is of extreme importance in ship construction on account of the tremendous stresses to which boats built for winter traffic are subjected. Only the very finest material can be used in such cases and had, for example, this vessel been launched without notice having been taken of the first crack, it would have been classed as 100 A-1, but the very first attempt at ice breaking would doubtless have ended disastrously.

Technical Museums, Frank E. Sanborn
Safety First as Applied to Traveling Cranes, Henry F. W. Arnold

COOLING TOWERS AND COOLING PONDS, Walter G. Stephan (4 pp., *gd*). The article discusses the design and use of cooling towers and cooling ponds in connection with the installation of condensing apparatus, the theory of their design and some tests made on cooling towers.

In the best commercial practice with the forced draft towers, it is possible to cool water to a temperature of about 15 deg. above the temperature of the dew point. With the natural draft tower, it is practical to cool to 20 deg. above the temperature of the dew point. The drop in temperature can be made considerable, but it seems to be more difficult to cool from 95 deg. to 85 deg., for example, than it is to cool from 125 deg. to 85 deg. with the same atmospheric conditions. The author gives formulas for the determination of the heat given up through convection and evaporation by water pumped over a cooling tower. With other conditions remaining the same, the temperature ratio of air-out to water-in represents the real efficiency of a cooling tower. In a well designed cooling tower, the humidity of the air leaving the tower is always 100 per cent. The terminal temperature difference will vary anywhere from 5 to 15 or 20 deg. Interesting tests on cooling towers were made by the Wheeler Condenser and Engineering Company of Carteret, N. J., the results of which are printed in Table 2:

TABLE 2 TESTS ON A FORCED DRAFT COOLING TOWER
AVERAGES OF THREE HOURS READINGS

Water				Air				Quantity measured by ane- mometer Cu. ft. per min.
Gal. per min.	Temperature Deg. Fahr.		B. t. u. per min.	Temperature Deg. Fahr.		Humidity Per Cent.		
	In	Out		In	Out	In	Out	
651	105	84.7	110,000	71	90	40	100	53,900
638	107.8	87.5	108,000	72	93	60	100	50,100
638	112	88.5	124,500	64	96	60	100	51,400
643	108.5	87	115,000	69	92	48	100	52,200
640	109.9	90.5	103,400	83	95	48	100	50,600
*632	116	98	94,800	43	101	75	100	23,500
*630	135	115.8	102,000	60	118	73	100	15,575

* Natural draft, fan not running.

The quantities of air were obtained by anemometers which were moved back and forth across the top of the tower at regular intervals and the results obtained were corrected so as to give the correct amounts entering the tower. The water was measured both by a Venturi meter and a calibrated Pitot tube.

In later experiments made with a view to increasing the efficiency of the towers, the quantity of air was not measured but the following results were secured in which it is to be noted that the temperature of the out-going air is only 3 deg. below the temperature of the in-flowing water. This

test was made on a large installation consisting of a special Wheeler-Balcke forced draft tower.

Water	Gal. per min.	3200
Temp. in	100 deg.	
Temp. out	97 deg.	
Air	Temp. in	91 deg. humidity 50 per cent.
	Temp. out	106 deg. humidity 100 per cent.

It is quite possible to cool water below the temperature of the air, this depending, however, on the air humidity. It is of course important to secure the lowest practical temperature of cooling water. A difference of 10 deg. lower initial temperature of the circulating water in a surface condenser may mean a difference between a vacuum of 27 in. and a vacuum 27¾ in., and ¾ inches of increased volume may mean quite a large saving in coal cost per year.

FIG. 9. CHARACTERISTIC CURVES OF CENTRIFUGAL PUMPS

Characteristic Curves of Centrifugal Pumps, F. William Greve, Jr. (abstracted)
Sewage Disposal Plant at Aberdeen, South Dakota, W. G. Potter

CHARACTERISTIC CURVES OF CENTRIFUGAL PUMPS, F. William Greve, Jr. (12 pp., 5 figs., *et*). The article treats of characteristic curves of centrifugal pumps as a means of illustrating a method of diagramming experimental data pertaining to centrifugal pumps. The curves deal with the head, speed, capacity, horsepower, input and output, and efficiency of a four-inch centrifugal pump.

The article contains five diagrams, of which only diagram Fig. 9 is reproduced here. Three series of curves have been plotted on it, the set showing the relation between head in feet and capacity in gallons per minute with the speed remaining constant for any one curve, and shows how the head decreases with increase of capacity except for very small discharges. At the same time, the maximum head does not

occur at the minimum discharge but at a point equal to about one-third of the maximum. If continued, these curves would have dropped on a line approaching the vertical. Another diagram illustrates the changes in efficiency for various values of capacity when computed for a constant speed. Up to a certain limit (variable) the maximum efficiency and capacity are found to increase with an increase of speed. For small discharges the efficiency is practically the same at any speed, and in general, the shape of the curves resembles a semi-ellipse. The horsepower input is found to increase with the discharge after a given speed until the point of maximum capacity has been reached when the curve becomes horizontal. The curves determining the range in head for various speeds with the discharge remaining constant approach closely those of straight lines and for large quantities may be assumed as such. In the diagram (a series of curves drawn from the upper left to the lower right end of the sheet show the horsepower required to discharge any quantity of water against any head and at any speed within the limits of the pump. The author fully explains the method of determining these curves and especially the use of interpolation.

The efficiency curves are similar to an ellipse, the major and minor axes of each curve intersecting in a common point of origin, which is also the point of maximum efficiency. The fact that these Iso-Efficiency curves are concentric is important, as when the efficiency is required for which no curves have been drawn, a new curve may be sketched in with reasonable accuracy. The advantages of representing the determinations of a pump by such curves lie in the fact that in any series of curves on the diagram, the curves are parallel or nearly so. This diagram may be considered to represent a map upon which the characteristics of the pump are indicated so that questions referring to the relations of speed, discharge, head pumped against, horsepower input and output may be answered by reference to it. The author points out that when more than one diagram is used in representing test results, there is danger of error when the eye is deflected from one diagram to another and that a single diagram is more convenient.

In the discussion which followed, Mr. H. S. Baker told of the wide adoption of centrifugal pumps in city water works. The city of Chicago has a number of such pumps, as well as the cities of Toronto, New York and Buffalo. The city of Cleveland has just purchased a twenty-five million gallon unit to work against a head of over 200 ft., while the city of Philadelphia has received bids for a number of centrifugal pumps to be driven by steam turbine.

Mr. Bowen told of a curious experience of a friend of his who has charge of seven large pumping stations with heads ranging from 85 to 340 ft. "He has no centrifugal pumps, but he made a statement to me which was indeed very interesting. From one of these stations, which is used for irrigation purposes, the water is taken off at several different levels, making several different heads; and the statement he made was, that when the water was taken off the discharge line at maximum head, the fuel consumption was quite a little greater than when a portion was taken off at high level and a portion at low level, and when the pumps were running at the same speed and therefore delivering the same volume of water. The head of pump, as indicated by gauges, was exactly the same in each case, which would indicate that the pumps were doing exactly the same work under the two

conditions, but the fuel consumption was different. If this is true, which is hard to conceive, then perhaps the testing of pumps in manufacturers' plants, where heads are created by a valve in the discharge line, may give results which will differ when the same head is obtained in actual operating conditions."

Permeability Tests on Gravel Concrete, Morton O. Withey (abstracted)
Arithmetical Machines, H. E. Goldberg
Reactions in a Three-Legged Stiff Frame with Hinged Column Bases, N. M. Stinson

PERMEABILITY TESTS ON GRAVEL CONCRETE, Morton O. Withey (46 pp., 20 figs. c.t.). The paper is a preliminary report on tests now conducted at the University of Wisconsin to determine the permeability of concrete to water, started at the suggestion of the Inspection Bureau of the Universal Portland Cement Company. The tests cover the effects on permeability of age, thickness, consistency of concrete, time of mixing, gradation of the aggregate, wet and dry sand, fineness of cement, and curing conditions. Only tests on gravel and sand aggregates are here considered, although work is being done on mixes containing sand and broken stone. The tests are somewhat unique because of the use of machine-mixed concrete and the employment of large specimens having a prescribed volume of concrete subjected to water pressure and the measurement of the water entering the specimens during a large number of hours.

The results of the tests are presented in the form of tables and sometimes curves. None of the test pieces showed visible signs of leakage, but from various evidence, it seems certain that the water went through the specimens and it is indicated that the rate of flow for the 20 to 50 hr. period on a specimen which has previously been subjected to water pressure is about the same as the rate for a similar specimen tested for the first time and it appears that the permeability of so-called impervious concrete is unaffected by age after being properly cured for one month. It appears that the rate of flow for specimens having no visible leakage is independent of the thickness, although it is barely possible that the pores in the top surfaces of the thin specimens were sufficiently compressed by the bending of the core under pressure to reduce the rate of flow. The effect of grading the sand and gravel into different sizes and recombining these sizes in such a way that the maximum density may be obtained, has been very carefully studied. If mixes containing practically the same proportion of cement by weight are compared, it will be found that the batches which were most impervious were of 1:5, 1:7 and 1:9, and most of the mixes have a higher proportion of fine particles than demanded by Fuller's theoretical curve.

In general, it was observed that the flows decreased as the density increased, and one of the figures indicates that either the ratio of the volume of the cement particles to the volume of air voids in a unit volume of concrete or the ratio of the volume of cement particles to the volume of air plus water voids furnishes an index of imperviousness, the former seeming a better index than the latter. It appears further that permeability is influenced much more than strength by a change either in the proportion of cement or in density.

From these tests the following conclusions applicable to concrete made of like materials may be drawn:

1. None of the concretes tested were absolutely watertight if we consider continuous flow into the specimen as proof of permeability, but the majority of the mixes were so impervious that no visible evidence of flow appeared. For most purposes such mixes can be considered watertight.
2. The visibility of dampness on the bottom of the specimens increased with the humidity of the air and the non-homogeneity of the concrete. The minimum rate of flow for which leakage was indicated was 0.00011 gal. per sq. ft. per hr.
3. In tests of nearly all of the properly made mixes of 1:7 proportions, or richer, the rate of flow for a fifty-hour period was less than 0.0001 gal. per sq. ft. per hr. under a pressure of 40 lb. per sq. in.
4. Through increasing the fineness of the cement, a reduction in the rate of flow and a considerable increase in the strength of a 1:9 mix were secured.
5. By grading the sand and gravel in accordance with Fuller's curve, it was possible to obtain practically watertight concrete of 1:9 proportions under pressure less than 40 lb. per sq. in. To secure such results, however, requires great care and careful supervision in mixing, in determining the proper consistency, in placing, and in curing the concrete.
6. In the proportioning of such materials as these, volumetric analysis coupled with a determination of the density and air voids yields very valuable information concerning the best proportions of sand and gravel for a given proportion of cement. If proportions must be selected arbitrarily a 1:1½:3 mix, by volume, is very impervious. It should be remembered, however, that the volume changes in rich mixes due to alternate wetting and drying are much greater than for lean mixtures. Consequently, due attention must be given to the provision of expansion joints and reinforcement in structures made of them.
7. The use of the proper amount of water necessary to produce a medium or mushy consistency is one of the most important conditions in securing impervious concrete, especially when lean mixtures are used. Dry mixtures cannot be sufficiently compacted in the molds and are more difficult to cure properly than the mushy mixtures. Although the use of a wet consistency does not materially affect the imperviousness of very rich mixes, such as 1:1½:3, it greatly increases the flow through a lean mix.
8. For lean mixes made from damp sand it seems advisable to mix longer than is now the common practice. These tests would indicate that for a mixer running at 30 r.p.m., a period of one and one-half to two minutes is required to secure thorough mixing of a 1:9 concrete, for a rich 1:1½:3 mix a one-minute period appears to be sufficient. The method of mixing in which water is first admitted to the mixer is to be condemned. A preliminary period of drying mixing lasting from 15 to 30 seconds seems desirable.
9. No stage or process in the making of impervious concrete is of more importance than curing. The results of these tests clearly demonstrate that premature drying destroys the imperviousness of 1:9 mixes, seriously impairs that of the 1:2:4 mixes and somewhat dimin-

ishes that of the 1:1½:3 mixes. For thin sections, not over 6 or 8 in. thick, the curing conditions should be such that a lean concrete will be kept damp for a period of one month and a rich concrete for at least two weeks. Even after a month of proper curing, complete desiccation of a lean mix composed of these materials produces an increase in permeability, but the effect on a rich mix is not marked.

10. In these tests, the imperviousness of the concrete increased rapidly with the age of the specimens for the first month; thereafter the change was not marked.
11. From the tests thus far made it seems probable that the permeability of lean concrete in a direction normal to the pouring is greater than in the direction of pouring.

MEETINGS

ATLANTA, SEPTEMBER 19

The second annual barbecue of the Affiliated Technical Societies of the City of Atlanta was held on the grounds of the City of Atlanta Pumping Station on September 19, 1914, with about 80 men present.

These meetings are held for the purpose of stimulating interest in the various local organizations, promoting the welfare of the national societies and advancing the interests of Atlanta. The following organizations were represented: the American Institute of Electrical Engineers, the American Society of Civil Engineers, the American Chemical Society, the Engineering Association of the South, the American Institute of Architects, and our own Society.

The meeting was called to order by A. M. Schoen, chairman of the executive committee of the affiliation, who briefly outlined the object of the meeting, its plans and expectations. He was followed by Paul H. Norcross, member of the Engineering Association of the South, who spoke upon the benefits of such gatherings and the fraternal spirit of the affiliation. Prof. T. P. Branch, a member of the American Society of Civil Engineers and of the Engineering Association of the South, spoke of the need of technical men in all technical positions. An interesting talk upon Physics and Chemistry, together with the importance of chemical manufacture, was given by Dr. J. T. Brogden, member of the American Chemical Society.

Gabriel R. Solomon, member of the American Society of Civil Engineers and of the Engineering Association of the South, then read a paper on the necessity for the engineer in public service, in which he said that the lack of recognition of the engineer by the public was largely his own fault because he is an indifferent citizen. The engineer needs to get into touch with life and to cease to hold himself aloof from public affairs while there are public questions of engineering interest which await an expression of intelligent and trained opinion.

Short talks were also given by Frederick Kloepper, of the American Institute of Architects, Prof. H. P. Wood, member of the American Institute of Electrical Engineers, R. D. Kneale, associate professor of civil engineering of the Georgia School of Technology, and Dan Cary, superintendent of parks and playgrounds. The last speaker laid stress on the necessity of expert advice in connection with city planning.

ST. LOUIS, OCTOBER 28

At a meeting of the Associated Engineering Societies of St. Louis, held on October 28, under the auspices of the local section of the Am.Soc.M.E., John Hunter gave a very interesting paper on The Development of the Central Station. The paper was illustrated by lantern slides, showing central stations in Boston, New York, Albany, Philadelphia, Detroit, Milwaukee, Chicago and St. Louis. The paper was discussed by those present.

BUFFALO, NOVEMBER 5

At a meeting of the Buffalo Engineering Society on November 5, J. Irvine Lyle of New York addressed the society on Industrial Ventilating and Cooling Equipment. Mr. Lyle gave some very interesting facts regarding some recent installations in cotton mills, tobacco manufacturing plants,

automobile plants, etc., for the purpose of air conditioning. His address was illustrated by lantern slides showing the construction and arrangements for the distribution of the pure air. There were about 120 members present.

NEW HAVEN, NOVEMBER 18

The Fall Meeting in New Haven was held at the Mason Laboratory of Mechanical Engineering, Sheffield Scientific School, on November 18. The following papers were presented: Electricity in Industry by Prof. Charles F. Scott, and Motor Applications; Arc Welding; Heat Treatment by W. L. Merrill of the General Electric Company. Following the presentation of the papers were a number of short addresses on applications of electricity by local manufacturing companies. The speakers were Mr. Flynn of the Royal Typewriter Company of Hartford on the Use of Electricity in Japanning Kilns, and Charles R. Underhill of the Acme Wire Company, New Haven, on the Use of Electromagnets in Manufacturing. W. S. Huson of Derby and C. H. Norris of New Britain discussed the papers.

Immediately after the afternoon session, there was an interesting demonstration in the laboratory of the variable speed hydraulic transmission manufactured by the Waterbury Tool Company of New Britain. This exhibit was arranged by courtesy of the Yale University Student Branch of the Society. Reynold Janney was in charge of this feature of the meeting.

J. Arnold Norcross was the Chairman of the evening session. Calvin W. Rice, Secretary of the Society, gave a talk on the Society and its work. The principal paper of the session was by S. S. J. Worgan of the Westinghouse Company on The Electric Motor in Manufacturing Plants. Short addresses were made by Prof. Scott, W. N. Polakov of the N. Y., N. H. & H. R.R. Company and Mr. Vandervere of the New Haven Gas Light Company and several others. The registration at the session was 150.

BOSTON, NOVEMBER 18

At a joint meeting of the Society with the Boston Society of Civil Engineers and the American Institute of Electrical Engineers on November 18, Henry M. Waite, city manager of Dayton, Ohio, gave an address on the new Commission-Manager Form of City Government.

He criticized at the outset the older federal form of city organization, and said that before a new system could be introduced the grasp of professional politicians must be loosened and ward and precinct organization relegated to the past. He called attention to the necessary allegiance of the political appointee to his political machine and the popular belief that the mayor and his administration should be blamed for all shortcomings, even though the chief executive were tied hand and foot and shorn of administrative power.

In Dayton, politics and municipal affairs had been divorced. Five commissioners were elected last November, all of whom are business men. This commission appointed a city manager and it is in the manager's power to appoint the five directors of law, finance, welfare, safety and service.

BUFFALO, NOVEMBER 19

At the meeting of the Buffalo Engineering Society on November 19, Prof. Dexter S. Kimball, professor of machine design and construction at Cornell University, addressed the Society on Appearance as a Factor in Design. Professor

Kimball treated his subject along broad lines, free from technicalities. There was an attendance of about 130 at the meeting.

CINCINNATI, NOVEMBER 19

At a joint meeting with the Engineers' Club of Cincinnati on November 19, Fred A. Geier, Associate Member of the Society, spoke on The Development of the Machine Tool Industry in Cincinnati. He traced the beginning of the industry to John Steptoe, who in 1850 built the first machine tool in Cincinnati. To Mr. Steptoe must be given the credit of having laid the foundation of one of the most important industries of Cincinnati, which has placed Ohio first in the production of machine tools. The second firm to install a department of machine tools was that of Niles and Company in 1865. This firm later developed into the Niles Tool Works and moved to Hamilton, Ohio. George Gray of this company remained in Cincinnati, however, and continued the manufacture of planers.

The speaker then outlined the conditions that make Cincinnati a good center for the manufacture and distribution of machine tools. He gave estimates of the volume of business at the present time, the number of men employed and the possibilities of development in the future.

ST. PAUL, NOVEMBER 19

A meeting of the Minnesota Branch of the Society was held at St. Paul on November 19. V. H. Roerich, City Chemist presented a paper on Coal Testing. The paper aroused considerable enthusiasm and discussion.

CHICAGO, NOVEMBER 20

The Chicago Section held its first meeting of the season on November 20. There was an informal dinner at which 140 were present. W. H. Winslow, the first speaker, explained the construction and operation of his new high-pressure boiler. He touched upon the possibilities of high pressures and of the Stumpf una-flow engine, which appears to be the prime mover best adapted for high pressure and super heat. His talk was illustrated by lantern slides.

Henry A. Allen, consulting engineer for the City of Chicago, and Robert Cramer, engineer of the Winslow Company, discussed the paper. Mr. Allen believed that the new boiler was specially adapted for portable use, such as for automobile trucks or buses and the large traction plow. Mr. Cramer believed that this boiler would soon be used by the largest power plants of the country and would show results at least 12 per cent higher than the best obtainable today.

The subject of boiler efficiency meters and European boiler practice was presented by W. A. Blouck, maker of the boiler efficiency meter. He explained briefly the principles of his meter with the red and blue fluids showing the drop in draft through the furnace and setting respectively. Mr. Blouck then spoke of European boiler practice. By means of slides, he showed the fine architectural design of the buildings and the efforts made to add to the appearance of the stack. Cross-sectional views showed the design generally followed and the small bunker capacity for coal. The latter was stored on the ground and conveyed to the boiler as needed. The injector draft chimney was in frequent evidence and ash-handling facilities were a negative quantity due largely to cheap labor. Small steam pipes with velocities up to 14,000 ft. per minute were also a feature.

The last part of the talk was devoted to the high-duty boiler with built in economizer. Evaporation tests of this kind of a boiler at Hamburg were presented. Joseph Harrington discussed some of the advantages of the German boiler, but he was of the opinion that the Blouck meter was very accurate and should be of great value in the boiler room.

Walter H. Green, chief engineer of the International Filter Company, spoke on mechanical filters, dwelling on methods of rating and some of the experiences that his company has had with prospective customers. Reference was made to the tendency of installing filters that were too small and also to the matter of using sand or quartz in the filter. Either may be used, but sand may be used in its natural state, whereas quartz must be ground. If sand is used, however, careful attention must be given to the choice of the sand, as it is quite essential that the particles be of uniform size.

PHILADELPHIA, NOVEMBER 21

A joint meeting with the Engineers' Club of Philadelphia was held on November 21. F. C. Hubley, Assistant Engineer of the American Bridge Company, gave a paper on Bituminous Coals; Predetermination of their Clinkering Action by Laboratory Tests. In a search for a specification that would really tell the operating properties of coal, the author discusses the clinkering of coal, which, as he shows, materially affects the capacity and efficiency of the plant, the amount of labor spent in cleaning fires and upkeep of fire boxes, and the smoke generation. The delays due to excessive clinkering may sometimes offset the advantage of a lower price of the coal. In order to specify the clinkering of coal in purchase contracts, however, a clear comprehension of this property has to be worked out, and methods developed for its laboratory determination, and the author shows that the former is possible by determining not the "fusible point" which, with a complex mixture such as coal ash, cannot be well defined, but the "fusible range" which is capable of precise definition and exact determination. He then proceeds to describe various methods of determining the fusing point of ash, such as the cone method, the fusiometer method, etc. He shows also that there is always a point capable of definite recognition in the fusing range, which although not the fusing temperature in the ordinary sense, is nevertheless a stage past that of incipient fusion and that this point of temperature bears a direct relation to the clinkering temperature in a boiler furnace, while the nature of the clinker formed, whether porous or spongy or close and hard, has as much to do with the detrimental effect on boiler operation as the question of temperature of formation. Fusing points were plotted against combination of the ash constituents so as to determine a relation between the approximate fusing point and the presence of two or more of the ash elements as determined by chemical analysis.

This very important subject was discussed by A. C. Wood, Professor Fernald, W. H. Fulweiler, E. M. Nichols, Dr. H. M. Chance, F. C. Freeman, Mr. Clonnell and E. B. Carter.

BUFFALO, DECEMBER 3

Ellis L. Howland addressed the meeting of the Buffalo Engineering Society on December 3, on the subject Practical versus Theoretical Ideals in Motor Truck Installation. Mr. Howland is automobile editor of the *Journal of Commerce* of New York City and he treated his subject from

the users or commercial standpoint and not from an engineering standpoint.

H. B. Alverson of the Cataract Power and Conduit Company and First Vice-President of the Engineering Society of Buffalo was in charge of the meeting. There were about 170 present.

SAN FRANCISCO, DECEMBER 8

At a meeting in San Francisco on December 8, the paper of the evening was read by A. H. Babcock, consulting electrical engineer for the Southern Pacific Company, on A Rational Method for the Treatment of Boiler Feed Water. Mr. Babcock described in detail the remarkable results that had been achieved in the treatment of the boiler feed water used at the Alameda power station for the Southern Pacific Company's suburban trains.

Mr. Geibel, who is Mr. Babcock's assistant and who is in direct charge of the experimental work showed in detail the methods that were pursued in overcoming the corrosive effect of waters carrying a large percentage of alkalinity, and also methods of testing the feed water for determination of the new treatment and the apparatus used for this purpose.

Mr. Twogood and Mr. Partridge also spoke briefly on the subject. The meeting was then open for discussion.

BOSTON, DECEMBER 9

At a local meeting in Boston on December 9, Mr. Nunez gave a paper on the Technology of Paper Making. In this paper, Mr. Nunez traced the different processes in the manufacture of paper and the different materials from which paper has been made from the time when it was first invented by the Chinese to the present time. He then discussed the quality, kinds, consumption and uses of paper. Paper is an extremely important article of commerce and has innumerable uses. The quality of any paper depends upon the use to which it is to be put, but the qualities which have to be considered and which govern its value for use are: strength, bulk, fibre direction, formation, finish, feel, texture, rattle, sizing, opacity, color, printing, erasing qualities, expansion and contraction, fibre composition, chemical residue and durability.

NECROLOGY

EDWARD DANIEL MEIER

In the death of Col. Edward Daniel Meier on Tuesday, December 15, 1914, after several months of illness, the engineering profession has lost one of its most honored members. He was president and chief engineer of the Heine Safety Boiler Company, president of The American Society of Mechanical Engineers in 1911, and for 20 years was one of the most active workers in the Society. He enjoyed an unusually wide circle of friends, as evidenced by the presentation at the Pittsburg meeting of the Society of an engrossed testimonial by a large number of his fellow members in celebration of his seventieth birthday.

He was born in St. Louis, Mo., May 30, 1841. At the close of a scientific course at Washington University, St. Louis, in 1858, he spent four years in Germany at the Royal Polytechnic College in Hanover, this being followed

by an apprenticeship at Mason's Locomotive Works, Taunton, N. J. In 1863 he enlisted in the Grey Reserves, the Thirty-Second Pennsylvania, which was attached to the army of the Potomac until after the Battle of Gettysburg. He subsequently served in the Second Massachusetts Battery, also in the United States Engineer Corps, and finally became lieutenant in the First Louisiana Cavalry, seeing much active service, and on May 30, 1865, receiving the surrender of Lieutenant-General John B. Hood and staff.

At the close of the war he entered the Rogers Locomotive Works, at Paterson, N. J., remaining one year. From 1867 to 1870 he was associated with the Kansas Pacific Railway, first as assistant superintendent of machinery, keeping open its Western communications when the bridges were swept away, designing, building and operating a mill for sawing, planing and turning the soft magnesian limestones by machinery, designing machine and car shops, etc., and subsequently becoming superintendent of machinery. He resigned to become chief engineer of the Illinois Patent Coke Company, leaving there in 1872 to assume the secretaryship of the McIer Iron Company and to build its blast furnaces. From 1873 to 1875 he directed the machinery department of the St. Louis Interstate Fair. During this time he became actively interested in the St. Louis cotton industry and was associated with the St. Louis Cotton Factory and with the Peper Hydraulic Cotton Press, for both of which he designed machinery for compressing cotton. In 1884 he organized the Heine Safety Boiler Company for the development in the United States of the water-tube boiler of that name, and continued as its president and chief engineer to the time of his death. He was also responsible for the introduction of the Diesel motor into the United States and until 1908 was engineer-in-chief and treasurer of the American Diesel Engine Company. One of his most important accomplishments was the design and installation of 10,000 h.p. boilers in the power house of the new Grand Central Terminal, New York.

Colonel Meier was lieutenant-colonel and later colonel of the First Regiment of the Missouri National Guard, serving about ten years, and was a member of the Grand Army of the Republic and of the Loyal Legion. He had been active in a number of professional organizations, serving in 1881-1884 as treasurer of the St. Louis Engineer's Club, in 1889-1890 as its president, and as secretary of the American Boiler Manufacturers Association. It was in the latter capacity that he drew up the Uniform American Boiler Specifications of 1898. He had been president of that organization and also of the Machinery and Metal Trades Association.

In The American Society of Mechanical Engineers, which he joined in 1891, he was active on many committees. He served as manager from 1895 to 1898, twice as Vice-President, from 1898 to 1900 and from 1909 to 1910, and as President in 1911. At the time of his death he was a member of the committee of the Society to formulate Standard Specifications for Steam Boilers, which had its inception largely through his efforts and which has accomplished a vast amount of work during the past three years.

A source of the greatest satisfaction to Colonel Meier, and a delightful memory to his many friends, was his connection with the remarkable tour through Germany in the summer of 1913 at the invitation of the Verein deutscher Ingenieure. Colonel Meier was chairman of the committee hav-

ing all the arrangements in charge, to a considerable extent was conductor of the party and many times was its spokesman. He often addressed his audience in German and his intimate knowledge of German history and accomplishment and his thorough appreciation of the industrial ideals of the nation added materially to the value and pleasure of the trip to the large number of engineers and guests who constituted the party.

AXEL H. HELANDER

Axel H. Helander was born in Vingaken, Sweden, in 1864, but came to America as a boy and spent most of his life in Pittsburgh. From July 1, 1906, to September 30, 1912, Mr. Helander was connected with the engineering department of the Mesta Machine Company after which he was with the William Tod Company, of Youngstown, Ohio, as second vice-president and general sales manager. Mr. Helander was the designer and inventor of many important engineering devices, chief among which might be listed the Helander condenser. He died at his home in Youngstown on October 17.

PERSONALS

Jay G. DeRemer has accepted a position with the American District Steam Company, North Tonawanda, N. Y. He was until recently affiliated with the United Light and Power Company, San Francisco, Cal., as chief engineer.

Ruland R. Shafter has accepted a position with the Chester Steel Castings Company as their New York manager.

Julius G. Berger has become connected with the Fulton Light, Heat and Power Company, Fulton, N. Y., as engineer.

Nicholas S. Hill, Jr., consulting engineer, has formed a partnership with Smith Farley Ferguson, and will continue to practice with him as a consulting hydraulic and sanitary engineer, under the firm name of Nicholas S. Hill, Jr., and S. F. Ferguson.

M. C. Maxwell, for the past seven years head of the Department of Applied Mechanics at Pratt Institute, Brooklyn, N. Y., and a Consulting Engineer, became identified with the Yale and Towne Manufacturing Company of Stamford, Conn., on July 1, 1914. He is now Superintendent of Power and Plant of that company, and is responsible for the power generation and distribution, the building maintenance, all new building construction, the general repairs and maintenance of all machinery, shafting, etc., throughout the plant. He also has charge of the tool department and is responsible for all tool designing, the machine shops for building tools, jigs, fixtures, dies, gages, etc., and the force shop.

E. L. Hill has recently accepted a position with the Hazard Manufacturing Company at Wilkes-Barre, Pa., in the capacity of Consulting Engineer and assistant to the Management. He was formerly with the American Steel and Wire Company, and for the past four years was superintendent of the company's insulated wire and power cable plant at Worcester, Mass.

Daniel W. Mead, having been absent from the United States during the summer as a member of the American National Red Cross Board of Engineers-Chinese River Conservancy, wishes to announce that he has returned, and is now prepared to serve his clients in making examinations, reports, plans and specifications for water power, water supply, flood protection, drainage irrigation, power plants and power transmission installations.

Dr. George F. Swain, Professor of Civil Engineering at Harvard University, delivered a lecture on Laws Hamper Improvement of Resources before the Technology Club of Syracuse on December 2. This was one of the series of lec-

tures by prominent men which are called the "John E. Sweet Lectures" in honor of the Club's first President.

J. H. Dougherty, formerly with the International Steam Pump Company, has been engaged by the Northern Equipment Company to take charge of the centrifugal pump design and the improvement and development of the well-known line of Erie Centrifugals.

Prof. C. R. Richards, Acting Dean and Director of the College of Engineering and Experiment Station of the University of Illinois, announces that there will be four vacancies for research fellowships to be filled at the close of the current academic year. These fellowships, for each of which there is an annual stipend of \$500, are open to graduates of approved American and foreign universities and technical schools. Appointments to these fellowships are made and must be accepted for two consecutive collegiate years, at the expiration of which period, if all requirements have been met, the Master's degree will be granted. Not more than half of the time of the Research Fellows is required in connection with the work of the Department, the remainder of the time being available for graduate study. Applications must be made not later than February 1 to the Director of the Station. Appointments are made in March and they take effect the first day of the following September.

Leo Loeb has been transferred from the Engineering Experiment Station at Annapolis, Md., to the Post Graduate Department of the United States Naval Academy at Annapolis, as professor of marine engineering.

Anderson Polk announces the opening of an office as testing and inspecting engineer, specializing in protective coatings and paint problems, with facilities for testing and analyzing cement, brick, iron, steel, paints and varnishes, waterproofing and all building construction materials.

James E. Allison, Chief Engineer of the St. Louis Public Service Commission, has been appointed as lecturer in Economics at Washington University. The lectures will deal with the economic principles underlying the regulation of public utilities. Some of the specific problems to be studied are the organization and operation of public utility corporations, their securities and the methods of financing them, and especially the method of valuing public utility properties for the purpose of taxation and rate regulation. Seniors in the Engineering School will be required to take this course. In order to encourage further the study of economics by the students, Mr. Allison has established a fund to be known as the "Allison Fund," the annual income of which is to be used either for awarding cash prizes or in such manner as in the opinion of the Dean of the School of Engineering and the head of the Department of Economics will best promote the object of the fund.

STUDENT BRANCHES

ARMOUR INSTITUTE OF TECHNOLOGY

On December 2, the Armour Institute of Technology Student Branch held its third meeting. Frederick Purdy, factory engineer for the Rayfield Carburetor Company gave a talk on Carburetion. Starting with the primitive carburetor of the surface type, Mr. Purdy showed the advance that has taken place by means of working models and slides. A number of curves from carburetor tests served to show the effect of various adjustments on the carburetor.

CARNEGIE INSTITUTE OF TECHNOLOGY

The regular monthly meeting of the Carnegie Institute of Technology Student Branch was held on November 11. After the regular meeting, the Mechanical and the Mining Clubs were jointly addressed by Mr. Hood of the mechanical engineering department of the Bureau of Mines. In a short time, the Bureau which will cooperate closely with the Institute in its work, expects to open its new buildings near the school.

In these buildings, will be located a mining, a mechanical engineering, a chemical, a miscellaneous mineral, a petroleum and an administrative department. In outlining the work of the Bureau, Mr. Hood said: "It shall conduct inquiries and scientific and technologic investigations concerning mining and preparation, treatment, and utilization of mineral substances with a view to improving health conditions and increasing safety, efficiency, economic development and conserving resources through the prevention of waste in the mining, quarrying, metallurgical, and other mineral industries; to investigate explosives and peat; and on behalf of the government to investigate the mineral fuels and unfinished mineral products belonging to, or for the use of the United States, with a view to their most efficient mining preparation, treatment and use; and to disseminate information concerning these subjects."

CASE SCHOOL OF APPLIED SCIENCE

At a meeting of the Student Branch of the Case School of Applied Science, a paper was presented by A. P. Armington, '15, on Efficiency Engineering. Three methods were taken up in detail and illustrated by examples: 1. Direct office control of production; 2. Time keeping with use of lapse time recorders; 3. Piece work systems and method of calculating rates. A discussion followed the presentation of the paper.

COLUMBIA UNIVERSITY

At a meeting of the Columbia University Student Branch on November 23, Prof. C. E. Lucke gave a lecture on Surface Combustion explaining its theory and design problem and showing the commercial advantage of this process of heating.

At a meeting on December 11, Arthur V. Fair of the S. F. K. Ball Bearing Company gave an interesting lecture on the Present Day Application of Ball Bearings. He spoke of the method of manufacturing and assembling ball bearings, their lubrication and care, the method of mounting them and their application to numerous industries such as the textile, machine tool, motor, locomotive, steel car, steel mill and automobile.

CORNELL UNIVERSITY

A meeting of the Student Branch of Cornell University was held on November 18. Prof. R. C. Carpenter spoke on the necessity for research in making possible the practical application of scientific theories and knowledge and the need of the college not for the spirit of research but for equipment upon which that spirit might work for beneficent end.

Prof. A. W. Smith, Dean of the College, spoke informally on the founding and ideals of the Am. Soc. M.E. and the mutual benefits enjoyed by the Society and its members.

At a meeting on December 16, Prof. D. S. Kimball lectured on primitive and recent mining machinery and methods. He spoke in particular of those in use in the development of the deep mines at Virginia City, Nev.

KANSAS STATE AGRICULTURAL COLLEGE

At a meeting of the Kansas State Agricultural College Student Branch on November 3, Professor Schluss gave an interesting paper in which he discussed some of the problems met with in the design of governors and the operation of different types of governors. Floyd Pattison, a graduate student, discussed the operation and manufacture of gas producers and emphasized many of the operation troubles of a producer gas plant.

At a meeting held December 3, Mr. Humman of the apprentice department of the Santa Fe Railway System discussed the efficiency movement and the wide field where efficiency could be practiced. Mr. Humman discussed in detail the necessity of cooperation of all employees for the best results and the advantages and disadvantages of day wages, piece work and the bonus system. In conclusion, he gave an outline of the apprentice school and its advantages to the men in the shops and to the employer.

W. W. Haggard, a student, read a paper which gave a

detailed description of the Dynamometer Car used by the Santa Fe Railway, the chronograph and records, and the way these records were taken and worked up by the office force.

LEHIGH UNIVERSITY

On November 10, the Student Branch of Lehigh University held a meeting at which the following papers were read: A Summer in the British Isles by D. Davidson '15 and Mechanical Engineering of Anthracite Coal Mines by W. H. Lesser, mechanical engineer for the Philadelphia and Reading Coal and Iron Company at Pottsville, Pa.

LELAND STANFORD JR. UNIVERSITY

At a meeting of the Leland Stanford Jr. University Student Branch on November 12, G. W. Dickie, Consulting Naval Engineer in San Francisco delivered a lecture on Safety at Sea. Mr. Dickie laid great emphasis on the importance of stability in steamship design.

OHIO STATE UNIVERSITY

On November 13, Edward P. Roberts, M.E. of the Roberts and Abbott Company, Consulting Engineers, Cleveland, Ohio, also Smoke Commissioner in the Department of Public Safety of that city, addressed the members of the student branches of the A.S.M.E. and the A.I.E.E. on the subject of Smoke Abatement.

Mr. Roberts discussed the various types of boiler settings for both the water tube and fire tube boiler and showed several arrangements that he had found to be very successful and comparatively cheap to install. He stated, however, that a setting which might give very complete and smokeless combustion under one set of conditions, might be wholly unsatisfactory if used under slightly different conditions, and emphasized the point that each case had to be dealt with separately. He named the requisites for complete combustion and then showed how the designers of the various types of stokers upon the market today had endeavored to make their stoker embody these principles.

The speaker gave figures showing the enormous losses which Cleveland and Pittsburgh attributed to the smoke nuisance. Cleveland's loss according to the 1908 report being \$6,000,000 or \$44 per family. This does not include the loss to plant and animal life, or the effect upon the respiratory organs of the people. He explained the methods used by the smoke inspectors of Cleveland in finding the offenders and the methods used in dealing with them, also the results of their work showing the great improvement they had effected in the abatement of the smoke from railway and yard locomotives. Mr. Roberts stated that the abatement of smoke was a problem well worth considering by all large cities, both from an economic and engineering standpoint. He claimed that the Cleveland department was paying several thousand per cent on the money invested in it.

The lecture was illustrated by lantern slides.

At a meeting on December 15, S. J. Lauer presented a paper on A Comparison of the Six-cylinder versus the Eight-cylinder Motor Car Motor. H. S. Vine gave a paper on The Oxy-acetylene Process of Welding. There was no discussion.

STEVENS INSTITUTE OF TECHNOLOGY

The Student Branch of Stevens Institute of Technology held its first lecture for the school year on December 8. Prof. William Kent, an alumnus of Stevens, a member of the American Society of Mechanical Engineers and a compiler of the well-known Handbook for mechanical engineers, gave a very interesting talk on Common Sense and Engineering, illustrating his subject with numerous appropriate stories. The meeting was especially honored by having two other prominent men in the American Society of Mechanical Engineers and in the engineering world, as speakers. Dr. Humphreys, President of Stevens Institute of Technology, gave a short prelude to the lecture by speaking of the engineer's place in the business world, while C. W. Rice, Secretary of the American Society of Mechanical Engineers, said a few

words on the Society's branches among students and the way in which they could be strengthened.

THROOP COLLEGE OF TECHNOLOGY

The first regular meeting of the Throop College of Technology Student Branch was held on December 18. C. H. McQuire, representative of the Los Angeles Branch of the Bosch Sulzer Diesel Engine Company, spoke on the Diesel Engine. Lantern slides were used to illustrate his talk.

UNIVERSITY OF CINCINNATI

The University of Cincinnati Student Branch held a meeting on November 28, at which D. J. Durrell, master mechanic of the Pennsylvania Railroad, gave a talk on the duties of the mechanical engineer, what conditions a mechanical engineer must face upon graduation, railroad work as applied to mechanical engineering and some of Mr. Durrell's experiences in that profession. The first two points the speaker discussed in detail and in the discussion of the third point, he included a brief history of the locomotive regarding its weight and its ability to devour space, also a summary of the transportation units and the traffic of the Pennsylvania Railroad during the year 1913-1914.

Prof. J. T. Faig, honorary chairman of the student branch, gave a short extemporaneous talk in which he pointed out the analogy of some of the speaker's remarks and his own teachings.

UNIVERSITY OF COLORADO

A meeting of the University of Colorado Student Branch was held on December 10. Charles M. Hampson, a consulting engineer from Colorado and a member of the Am Soc. M. E., delivered a lecture to the students on the ethical side of engineering, or as he said that he liked to call it, the "side of the square deal." In tracing the growth of the profession, he showed that the responsibilities of the mechanical engineer of today are much greater than those of the mechanical engineer in the earlier days of the profession.

UNIVERSITY OF KENTUCKY

The first regular meeting of the University of Kentucky Student Branch was held on November 28, at which the following officers were elected: Minott Brooke, president; Y. B. Arnold, vice-president; P. T. Taylor, treasurer, and T. R. Munson, secretary.

Prof. F. P. Anderson, Dean of the College of Mechanical and Electrical Engineering, spoke on the relation of the branch with The American Society of Mechanical Engineers and the advantages of the young engineer by belonging to the Society.

On November 4, Dr. A. S. McKensie, Dean of the Graduate School, spoke to the branch on the value of research work to the engineer.

UNIVERSITY OF MAINE

At a meeting of the University of Maine Student Branch on December 17, four reels of moving pictures which belonged to the National Tube Company showed the ore as it was taken from the mines in the Lake Superior region, its transportation to the company's factories and the different processes through which it goes before it finally becomes the tube product.

UNIVERSITY OF MICHIGAN

A meeting of the University of Michigan Student Branch was held on December 5. F. R. Still of the American Blower Company gave a short talk on The Application of Blowers to General Engineering Practice which included the ventilation of public buildings, the necessity of humidifying the air in such buildings for the health of the inhabitants, a process of air drying which is being tried in the west on some of the fruits instead of the regular sun drying, and a continuous process for manufacturing of bricks which has proved successful on a great many kinds of brick.

Mr. Still showed slides illustrating different types of blowers and their various applications, also some curves from which these fans are designed to meet the requirements.

UNIVERSITY OF MINNESOTA

At the November meeting of the Student Branch of the University of Minnesota, Prof. C. F. Shoop of the Department of Experimental Engineering was selected to Honorary Membership.

Messrs. C. J. Snow and E. H. Roberts presented papers on the Heating and Ventilating of the New Saxe and Shubert Theaters. The Saxe Theater, a motion picture house with a seating capacity of 1400 is heated and ventilated by the plenum system. The fresh air is taken in at the roof level, and taken down a vertical shaft from which it passes through the temperature coils which consist of 918 sq. ft. of "Vento" heaters, arranged two stacks deep and two tiers high. It next passes through the air washer which is of the "Webster" make, and from there through the re-heating coils which consist of 1836 sq. ft. of "Vento" heaters arranged four stacks deep and two tiers high. The air is then drawn through the fan and from there is sent to the distributing branches. The building is provided with automatic temperature and humidity control, making the plant entirely automatic. Steam is purchased from an outside source at the rate of \$5.5 per 1000 lb. of condensate.

The Shubert Theater heating plant consists of a low pressure steam heating plant and plenum system of ventilation. The heating system consists of 66 ft. by 16 in. tubular boiler, on a two pipe steam system with 560 sq. ft. direct radiation. The ventilating system consists of a 60 in. steel plate fan, directly connected with a 10 h.p. motor running at 250 r.p.m. Air is drawn from street level through a bank of coils containing approximately 4000 lineal ft. of 1 in. pipe, which is equivalent to 1561 sq. ft., having free area of 23.1 sq. ft. Air is discharged into a large plenum chamber extending under the greater part of the auditorium. From here it goes directly into the auditorium through about 400-9 in. by 6 in. openings with hoods, so that the discharge is parallel to the floor. Exhaust is by means of natural draft. The peculiarities of the plant are that the air velocity is reduced both in coils and chamber, and dust is thus eliminated without special apparatus. The efficiency figured on a B.t.u. basis is 67 per cent, exclusive of boiler.

At the December meeting of the branch, M. E. Crosby gave a general outline of the flour industry. He traced the wheat through the different processes which it undergoes from the time it enters the mill until it is turned out as one or more different grades of flour.

In conjunction with Mr. Crosby's talk, A. P. Mason gave a description of a grinding machine which is used to grind screenings. The principal feature of this machine is a perforated cylinder of hardened steel against which the stock is thrown tangentially at the high velocity. A shearing effect is thus produced which reduces the stock to the desired size.

UNIVERSITY OF MISSOURI

At a meeting of the University of Missouri Student Branch on December 3, Messrs. Haney and Royse were appointed to investigate affairs pertaining to the society's proposed inspection trips to St. Louis, Mo., and other nearby cities.

Ralph Coatsworth read a paper on the new 8 cylinder "V" type internal combustion motor which is now used by the Cadillac Motor Company.

UNIVERSITY OF NEBRASKA

At a meeting of the University of Nebraska Student Branch on December 1, Prof. B. F. Raber of the Department of Mechanical Engineering who spent the summer in the turbine department of the Westinghouse manufacturing plant at Pittsburgh, Pa., gave an illustrated lecture on the Pittsburgh District.

The town proper is located at the point which is formed by the junction of the Allegheny and Monongahela Rivers, and the district includes the area within a radius of about forty miles of this point. The country is very hilly and the flood plains of the rivers are bordered by high cliffs. On account of the rugged nature of the country, the district is divided into an enormous number of small towns and cities.

The mills that are scattered through the country and along the rivers together with their employees form towns by themselves. One of the largest of these outside of Pittsburgh proper is Wilkensburg, where most of the Westinghouse employees make their homes. It has a population of about 20,000. Other large and thickly populated parts are So. Pittsburgh which is across the Monongahela River from the Point and Allegheny which is across the Allegheny River from the Pittsburgh District. The population of the Pittsburgh District is over 4,000,000.

Professor Raber gave views of Pittsburgh showing the business and residence districts, wharves, private residences, parks and the buildings of the University, including the exterior and interior of the Carnegie Institute and School of Technology. He showed some views of places outside of Pittsburgh proper which included all of the larger steel and iron mills, the plants of the American Signal Company and the Westinghouse Company. He described their products, the number of employees and the pay roll. The turbines and engines of the Westinghouse type were shown both complete and in course of construction. One of these was being built for the U. S. S. "Neptune."

WORCESTER POLYTECHNIC INSTITUTE

At the meeting of the Worcester Polytechnic Institute Student Branch on December 4, H. Clayton Kendall of the Rockwood Sprinkler Company gave an illustrated lecture on Factory Fire Protection. After a brief review of the amount of property loss by fire, the speaker described the mechanical means taken to put water on a fire in its incipient stage. The foremost mechanical device at the present time for doing this according to Mr. Kendall is an automatic sprinkler head kept properly supplied with pressure water. In the lantern slides shown by Mr. Kendall, the effect of an automatic sprinkler system as preventing serious conflagrations in buildings thus equipped was clearly presented.

YALE UNIVERSITY

A meeting of the Yale University Student Branch was held on November 13. At this meeting, Reynold Janney, Vice-President and Chief Engineer of the Waterbury Tool Company, presented an illustrated paper on the Hydraulic Variable Speed Gear manufactured by the company with which Mr. Janney is connected. Mr. Janney's address was divided into three parts as follows: a. the advantages or practical aspect; b. the mechanical construction; c. the mathematical problems connected with the gear.

After the lecture, Mr. Janney demonstrated one of the gears which was mounted, together with its motor as a single unit.

EMPLOYMENT BULLETIN

Note: In sending applications stamps should be enclosed for forwarding.

The Secretary considers it a special obligation and pleasant duty to be the medium of securing positions for members, and is pleased to receive requests both for positions and for men. The published notices of "men available" are made up from members of the Society. Notices are not repeated except upon special request. Names and records are kept on the office list three months, and if desired must be renewed at the end of such period. Copy for the Bulletin must be in hand before the 12th of the month.

POSITIONS AVAILABLE

1201 Representatives wanted in the principal cities of United States to sell vacuum heating specialties on commission. Apply through Society. Applicant will please state what similar specialties, if any, he has previously sold.

1202 Several good draftsman - salaries \$100 to \$125 per month. Location South Bethlehem, Pa.

1203 Superintendent and master mechanic, man of refinement, preferably graduate of M.I.T., with textile mill experience, and one who can take a position of prominence in company and city. Salary about \$2500. Age 30 to 35. Apply through Society.

1204 New England University desires assistant to the

instructor in charge of the mechanical laboratory and in correcting of problems in thermodynamics, mechanism, and machine design. Desires a man with initiative and a desire to make good.

1206 Assistant in the boiler insurance department of a casualty and surety company; salary \$1200 per year to start with reasonable expectation of steady advancement; essential requirements, knowledge of engines and boilers and ability to conduct correspondence. Young man preferred. Location New York City. Apply through Society.

1239 Man capable of taking charge of the production of a manufacturing department; requires experience in stamping, drawing and forming of steel; other desirable qualifications are ability to meet men in trade and to estimate orders and handle correspondence. Location Connecticut. Apply through Society.

1253 High class man to represent a Michigan company in the City of New York; must show a splendid record in the selling end of the power plant field, have a thorough acquaintance with the consulting engineering profession and must be a high-class salesman in the full sense of the word. Apply through Society.

1254 Competent young man to fill the position of assistant superintendent in a shop where a variety of heavy machinery is manufactured. Name confidential. Apply through Society.

01 Two competent detail draftsmen, experience in sugar house work; must be rapid and accurate. Location New York. Apply through Society.

02 A good opening for an engineer thoroughly experienced in design and operation of hot bulb two-cycle oil engines. Should be familiar with both foreign and domestic practice. Location, Illinois. Apply through Society.

04 Large New Jersey plant wants a technical graduate, not over 30 years of age, to serve an apprenticeship and learn the technical and executive business of an important department, with a view, if successful, of becoming assistant superintendent. Give full statement of record, accounting for all of time since leaving college. Starting salary, \$25.00.

07 Chief Draftsman, high grade practical machine designer, experienced in machine, pattern shop and drawing room; must be a man who can make practical designs from a shop standpoint, that goods may be manufactured cheaply and be of such grade as to meet the best competition. Position permanent for man of ability. Location, Missouri.

08 Young shop superintendent and engineer, one who has had considerable experience and is thoroughly familiar with machine work, and can also take charge of the drafting room, with ability to cut down manufacturing costs. Location, Illinois. Apply through Society.

MEN AVAILABLE

A-1 Junior member, age 25, experienced in factory work, machinist, tool and die-maker, designing of tools, machines, mill buildings, power plants and their equipment, also reports, factory accounting and reorganization, desires position in charge of production or in engineering department.

A-2 Mechanical engineer 1914 graduate with new untried idea for kerosene carburetor, desires position in experimental department of gas engine company willing to try out his idea.

A-3 Member, graduate engineer, experience as efficiency engineer, also design and supervision of installation of mechanical equipment of buildings, power plants and central heating systems, desires position with consulting engineer, architect or private concern.

A-4 Member, age 35, technical graduate, ten years experience in civil, mining and mechanical engineering, steel plant and general construction work desires executive or

sales position where broad experience, energy and tact will be required with good chance for advancement. At present employed.

A-5 Technical graduate, Junior member, age 25, three and one-half years practical experience in engineering, desires position in selling department of manufacturing concern. At present employed in New York.

A-6 Associate, age 43, with wide manufacturing and considerable commercial experience would consider a position of responsibility in a large manufacturing concern or power company, or the general managership of a small growing company with good possibilities.

A-7 Member, graduate mechanical engineer, 20 years experience as designer and draftsman of simplex and duplex steam pumps, desires position as designer or chief draftsman.

A-8 Junior member, M.E., technical graduate, age 27, married, three years experience in drafting, machine design and laying out of hydro-electric plants, desires position with opportunity for experience and advancement. Location immaterial. At present employed.

A-9 Member, age 34, M.I.T. graduate, married, for past six years with leading engineers and architects in the East, designing steam power plants, heating and other piping systems and inspecting constructions and equipment, at present employed as superintendent on construction and equipment of large mill and power plant, desires position along similar lines.

A-10 Technical graduate, age 32, nine years experience in mechanical department of large western railroads as chief draftsman and mechanical engineer, three years as construction engineer and superintendent on power plant and shop construction. Has specialized in crude oil burning arrangements as applicable to locomotives and stationary boilers, shop, and power plant design, construction and equipment and electrical installations. Speaks Spanish; would consider foreign location.

A-11 Member, technical graduate, with commercial training, speaking five languages, fully conversant with Latin and South American trade conditions, 18 years varied experience in design and construction of machinery and buildings, remodeling, maintenance and operation of industrial plants and equipment; systematizing of shops and processes along scientific management lines, testing and general plant engineering; familiar with handling men, drawing up contracts, purchasing equipment and material, appraising properties, modern methods of manufacturing and marketing products, desires to become identified with manufacturing or industrial plant in responsible administrative or executive position. At present employed.

A-12 Member, wide experience in design and construction of factory buildings and power plants, purchasing of supplies and equipment for economical production, designing of special tools and machinery, has held positions as manufacturing superintendent, shop manager and chief engineer for large corporations, desires position with manufacturing or contracting company or firm of consulting engineers.

A-13 Associate-Member, engineering graduate, two years teaching experience, now employed as Diesel engine designer, wishes position of responsibility with manufacturers of oil or gas engines. Eastern location preferred.

A-14 Member, graduate of Stevens '97, broad experience in machine shop practice, superintendent of construction, field work, test of prime movers, boilers and power house design; for many years with leading consulting engineers and contractors in New York as designing engineer and draftsman, desires position of similar nature with engineering firm.

A-15 Engineer with experience in design and construction of special metal working machinery and tools for economic manufacture can offer an improved design of power punching and stamping presses in several sizes.

A-16 Member, Cornell graduate, mechanical and electrical engineer with extensive training and experience in designing, constructing, maintaining, operating and managing, desires a position as mechanical, electrical, efficiency or office engineer, superintendent, manager or purchasing agent of an engineering corporation.

A-17 Member of Society experienced in employment methods will take entire charge for large corporation hiring employees and supervising personal efficiency methods.

A-18 Member, Cornell graduate, fourteen years experience as machinist, material inspector, testing engineer, draftsman, mechanical engineer and salesman, desires position as sales engineer or engineering of tests. Location immaterial, western states preferred. At present employed as salesman of power plant machinery.

A-19 Mechanical engineer, Stevens graduate, age 30, married, six and one-half years varied experience, specialized in pressed steel, both light and heavy, at present holding responsible executive position as plant engineer with small manufacturing concern, desires a position along similar lines, or one as assistant to superintendent or manager with company offering good chances for advancement.

A-20 Designing and contracting engineer desires to increase his clientele among concerns in need of engineering service in the field of machinery for the expeditious handling of materials of which he has made a specialty.

A-21 Junior, age 31, married, with 12 years experience in heating, ventilating and machine design, estimating, selling, complete knowledge of shop and office methods, capable of taking charge of designs and specifications wishes position with concern where efforts and loyalty are appreciated.

A-22 Member, M.I.T. graduate in mechanical engineering with post-graduate course in electrical engineering, twenty years experience in design and construction of machinery and building, manufacturing, systematizing, accounting, refrigeration and as consulting engineer, desires permanent position in New York.

A-23 Graduate mechanical engineer experienced in drafting, machine shop, foundry work and as a salesman, desires position with manufacturing concern in any department where there is opportunity for advancement.

A-24 Member, experienced in designing of locomotives and cars, specialized in efficiency work and the handling of men, expert examinations of property, desires position as manager of large manufacturing business.

A-25 Student member, age 23, technical graduate with shop and drafting experience, desires position.

A-26 Junior technical graduate in mechanical and electrical engineering, 12 years experience in design, construction, maintenance and operation of power houses and substations, high voltage transmission lines, design and erection of steam and water piping layouts, wiring and installation of machinery, pumps, engines, etc., desires position with large firm. Location New York. Salary \$10.

A-27 Junior, graduate mechanical engineer with varied experience desires position with concern manufacturing or selling automobiles or automobile accessories. Willing to start as a demonstrator. Speaks German. Location immaterial.

A-28 Associate, age 40, Lehigh University graduate in mechanical engineering, 18 years experience in mechanical, civil and electrical work, including design, construction and operation of power plants, electric railway track work, industrial buildings, handling correspondence, purchasing, etc., for past seven years in responsible charge of work, wishes executive position of responsibility. Now temporarily employed.

A-29 Member, technical graduate, 16 years railroad experience in motive power department, including shops and

drafting room and mechanical engineering, desires similar position or one as assistant superintendent of motive power. Location immaterial.

A-30 Graduate mechanical engineer, three years practical experience in shop work, design, superintending, cost and sales work, and as head draftsman in engine and boiler works and shop superintendent in gasoline motor works. Moderate salary, location immaterial.

A-31 Junior, technical graduate in mechanical engineering, age 30, five years experience in mechanical and construction work, desires responsible position with manufacturing or construction firm.

A-32 Graduate mechanical engineer, four years practical experience desires position with manufacturing, engineering, contracting or consulting firm. Good future rather than salary considered.

A-33 Superintendent experienced in modern shop and manufacturing practice, good organizer who can produce interchangeable work at low cost and who understands cost keeping and the various systems of paying for labor.

A-34 Associate-Member having organization with several engineers, desires additional Chicago agencies in lines usually referred to architects and consulting engineers.

A-35 M.I.T. graduate in mechanical engineering, single, having specialized in the manufacture of raw and white sugar in the tropics; thorough knowledge of Spanish and tropical business methods. Now employed as chief engineer of large sugar house in the tropics.

A-36 Member, graduate M.I.T. in mechanical engineering, age 39, married, experienced in manufacture of ordinance-rifled arms, shell and ammunition, design and construction of dry docks—wood, stone and floating, pumping plants, power houses, and shops; acid and electrolytic refineries; wire and cable plants; reinforced concrete and general building construction with complete electrical and mechanical equipment for same; nine years general and seven years consulting engineering; position to be executive, superintendent or engineer of construction. Location preferred, Eastern Canada.

A-37 Mechanical and electrical engineer, with a number of years experience in installation and operation of power plant and factory equipments, building construction and maintenance of factories and buildings, is qualified by experience to serve as construction or operating engineer, superintendent of manufacture, or appraisal of power and manufacturing equipment. Permanent position desired, but will not refuse reasonable offer for temporary work.

A-38 Energetic young man, age 26, graduate M.E., three years experience, desires position in mechanical engineering line. Location immaterial.

A-39 Junior member, age 26, experienced in design, construction and operation of steam engines, boilers, refrigerating machinery and power plant accessories, recently employed on design of Panama Canal coaling stations, desires position.

ACCESSIONS TO THE LIBRARY

WITH COMMENTS BY THE LIBRARIAN

This list includes only accessions to the library of this Society. Lists of accessions to the libraries of the A. I. E. E. and A. I. M. E. can be secured on request from Calvin W. Rice, Secretary of Am. Soc. M. E.

AMERICAN BUREAU OF SHIPPING. Rules for Building and Classing Vessels. *New York, 1911.* Gift of American Bureau of Shipping.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS. Transactions, vol. 1913. *New York, 1911.* Gift of Institute.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS. Report (preliminary) of the Special Committee on the Construction of Steam Boilers and for their care in service.

— — Recommendations for a Model Engineers' and Firemen's License Law, a Model Boiler Inspection Law, and a Code of Practical Boiler Rules.

— — Recommendations of the Boiler Code Committee for a Model Stationary Boiler Inspection law, a Model Stationary Engineers' and Firemen's License law, and a code of practical rules. (Progress Report.) Gift of A.S.M.E.

AMERICAN TRADE INDEX, 1911-13. Domestic edition. *New York, 1913.* Gift of A.S.M.E.

BAYLOR UNIVERSITY. Annual Report of the President and Trustees, 1913-14. *Waco, Texas, 1911.* Gift of University.

CAMBRIDGE (MASS.) WATER BOARD. Annual Report, April 1, 1913-April 1, 1914. *Cambridge, 1914.* Gift of Cambridge Water Board.

CITY OFFICIALS OF THE UNITED STATES, 1914. Compiled by Engineering News. Gift of A.S.M.E.

EDWARDS' 900 EXAMINATION QUESTIONS AND ANSWERS FOR ENGINEERS AND FIREMEN. *Philadelphia, 1912.*

ELEMENTARY ELECTRICITY AND MAGNETISM, Wm. S. Franklin and Barry Macnutt. *New York, The Macmillan Co., 1911.* Gift of Publishers.

An elementary textbook for schools of technology and colleges. Remarkably clear in language. W. P. C.

FILTERS AND FILTER PRESSES FOR THE SEPARATION OF LIQUIDS AND SOLIDS, from the German of F. A. Bühler. *London, 1911.*

FORMS USED IN CONNECTION WITH OHIO ELECTRIC LIGHT COMPANIES. Gift of L. B. Webster.

HAWAIIAN VOLCANO OBSERVATORY OF THE MASSACHUSETTS INSTITUTE OF TECHNOLOGY. Report January-March 1912.

— — Special Bulletin, An address delivered at a meeting December 11, 1913, by T. A. Jaggard, Jr. 1913.

— — Weekly Bulletin, vol. 2, nos. 1-25, 1914. Gift of Massachusetts Institute of Technology.

HYDRAULIC TURBINES, R. L. Daugherty, ed. 2. *New York, 1911.*

INSTITUTION OF MECHANICAL ENGINEERS. General Index to Proceedings, 1901-1910. *London.* Gift of J. Inman Emery.

THE KELVIN LECTURE, S. P. Thompson. Delivered April 30, 1908. Gift of C. W. Rice.

MACHINE DESIGN, CONSTRUCTION AND DRAWING, H. J. Spooner, ed. 3. *New York, 1913.*

MATERIALS OF MACHINES, Albert W. Smith, ed. 2. *New York, 1911.*

MECHANISMS OF STEAM ENGINES, Walter H. James and Myron W. Dole. *New York, J. Wiley & Sons, 1911.* Gift of Publishers.

An elementary treatise on the kinematics of the steam engine for use by students. W. P. C.

MODERN FACTORY, Geo. M. Price. *New York, 1911.*

MOTORCYCLES, SIDE CARS AND CYCLE CARS, Victor W. Page. *New York, 1911.*

THE MOST IMPORTANT QUESTION OF THE AGE: IS THE EFFICIENCY OF A THERMODYNAMIC REVERSIBLE CYCLE INDEPENDENT OF THE WORKING MEDIUM, J. T. Wainwright. *Chicago, 1911.* Gift of author.

THE NAVAL CONSTRUCTOR, George Simpson. A vade mecum of ship design. ed. 3. D. Van Nostrand Co., New York, 1911. Gift of Publishers.

This is the third edition of the author's work. It is replete with information of use to the naval constructor and contains much material which might be of great value to any engineer engaged in construction. The author has compiled much out of the way information. W. P. C.

NIAGARA STATE RESERVATION COMMISSION. 30th Annual Report, 1912-13. Albany, 1914.

A History, by Chas. M. Dow. Albany, 1911. Gift of Commissioners of the State Reservation at Niagara.

SIMEON NORTH, FIRST OFFICIAL PISTOL MAKER OF THE UNITED STATES, S. N. D. North and Ralph H. North. A Memoir. The Rumford Press, Concord, N. H., 1913. Gift of S. N. D. North.

Such monographs as this are too few in the United States; the majority of our people are too busy to make historical researches. Mr. North's record is very interesting, as bearing on the history of early American manufacturing. The Librarian wishes to thank the authors for this important contribution to a subject which has not received the attention it deserves. W. P. C.

OHIO GAS LIGHT ASSOCIATION. Question Box. 19-22d Annual Convention, 1903-06. Gift of C. W. Rice.

OIL, PAINT AND DRUG REPORTER. GREEN BOOK FOR BUYERS. September 1914 edition. New York, 1914. Gift of Oil, Paint & Drug Reporter.

POLYPHASE CURRENTS, Alfred Still. ed. 2. New York, The Macmillan Co., 1911. Gift of publishers.

This is the second edition, largely rewritten and rearranged. W. P. C.

PRACTICAL TREATISE ON MILLING AND MILLING MACHINES. Providence, Brown & Sharpe Mfg. Co., 1911. Gift of Publishers.

Published, not as a trade catalogue, but with the idea of presenting such information on the care and use of these machines as will be of assistance to beginners and practical men. There are extensive tables. W. P. C.

PRIMER OF SCIENTIFIC MANAGEMENT, Frank B. Gilbreth. New York, 1914. ed. 2. Gift of author.

The new edition is issued a little more than two years after the old one, showing a constant demand for an elementary treatise on the subject. W. P. C.

PUMPING BY COMPRESSED AIR, E. M. Ivins. New York, 1911.

RECALL OF JUDGES AND RECALL OF JUDICIAL DECISIONS. A discussion at the annual meeting of the Illinois State Bar Association. Chicago, 1912. Gift of Illinois State Bar Association.

SAW MILLS, THEIR ARRANGEMENT AND MANAGEMENT, M. P. Bale. ed. 4. London, 1911.

SCIENCE OF KNITTING, Ernest Tompkins. New York, 1911.

SPUR AND BEVEL GEARING. New York, 1911.

SURGE TANK PROBLEMS, Franz Prasil. Toronto, 1911. Gift of E. R. Weinmann.

TESTING OF WOOD PULP, Sindall and Bacon. A Practical Handbook for the Pulp and Paper Trades. London, 1912.

TUFTS COLLEGE. Announcement of the Engineering School, 1914-15. Tufts College, Mass., 1911. Gift of Tufts College.

DER VERKEHR. JAHREBUCH DES DEUTSCHEN VERKEHRS. 1914. Jena, 1914.

WELDING. INSTRUCTION PAPER, George W. Craycus. Chicago, American School of Correspondence, 1911. Gift of author.

Covers all forms of welding, blacksmith's welds, brazing, soldering, gas welding, electric welding, etc. A useful little manual. W. P. C.

ZEITSCHRIFT FÜR PHYSIKALISCHE CHEMIE. vols. 1-52. Leipzig, 1887-1913.

— — — Namen und Sachregister. vols. 1-50. Leipzig, 1903-04, 1910-11.

GIFT OF AMERICAN SOCIETY OF CIVIL ENGINEERS

ASSOCIATION OF ONTARIO LAND SURVEYORS. Annual Report, 1913, 1914.

CANADA. DEPARTMENT OF THE INTERIOR. Report of Progress of Stream Measurements. 1912.

CANADA. DEPARTMENT OF RAILWAYS AND CANALS. Canal Statistics for the season of Navigation. 1912.

CANADA. DEPARTMENT OF PUBLIC WORKS. Ottawa River Storage. Progress Report. 1909-1910.

— — — Reports of the Ottawa River Storage and Geodetic Levelling from Halifax, N. S., to Rouses Point, N. Y. vol. 11, 1912.

— — — Reports of the Ottawa River Storage and notes on a visit to the Panama Canal, also Geodetic Levelling between Stephens, Minn., and Winnipeg Beach, Man. vol. 11, 1913.

CHICAGO, ROCK ISLAND AND PACIFIC RAILWAY COMPANY. 33d Annual Report, 1913.

CHICAGO, MILWAUKEE AND ST. PAUL RAILWAY COMPANY. 49th, 50th, Annual Report, 1913, 1914.

CLASSIFICATION OF OPERATING EXPENSES OF CARRIERS BY WATER, AS PRESCRIBED BY THE INTERSTATE COMMERCE COMMISSION. Wash., 1910.

CONNECTICUT. RIVERS, HARBORS AND BRIDGES COMMISSION. Report, 1912.

GREAT NORTHERN RAILWAY COMPANY. 24th Annual Report, 1913.

HAWAII. SUPERINTENDENT OF PUBLIC WORKS. Report to the Governor for two years ending June 30, 1912.

ILLINOIS AND MICHIGAN CANAL. Special Report. 1912.

INDIANA SANITARY & WATER SUPPLY ASSOCIATION. Proceedings of 6th Annual Convention. 1913.

THEORY OF ARCHES AND SUSPENSION BRIDGES, J. Melan. 1913.

MONTANA. STATE ENGINEER. Biennial Report. 1911-12.

NATIONAL ASSOCIATION OF RAILWAY COMMISSIONERS. Select List of references on the Valuation of Public Service Corporations.

NEVADA. PUBLIC SERVICE COMMISSION. Case No. U 15. City of Ely, complainant, vs. Ely Light and Power Company. 1913.

NEW MEXICO. SURFACE WATER SUPPLY. Report 1911-12, 1913.

NEW MEXICO. STATE MINE INSPECTOR. 2d Annual Report, 1913.

NEW SOUTH WALES. METROPOLITAN BOARD OF WATER SUPPLY AND SEWERAGE. 24th Report, 1912.

NEW YORK STATE. JOINT COMMITTEE OF THE LEGISLATURE ON THE CONSERVATION AND UTILIZATION OF WATER POWER. Report, 1913.

OHIO. SEWAGE TREATMENT AND TRADE WASTES. Report to the Director at Akron. 1912.

ONTARIO. HYDRO-ELECTRIC POWER COMMISSION. 5th Annual Report, 1912.

PANAMA RAIL ROAD COMPANY. 6th Annual Report of the Board of Directors to the Stockholders, 1913.

PAST, PRESENT AND FUTURE, WATER SUPPLY OF SAN FRANCISCO, H. Schussler. 1908.

——— Water Supply of San Francisco, Cal. 1906.

SHOULD PUBLIC SERVICE PROPERTIES BE DEPRECIATED TO OBTAIN FAIR VALUE IN RATE OR REGULATION CASES? J. E. Allison. Report of St. Louis Public Service Commission, Sept. 11, 1912.

SPECIFICATIONS FOR MAPS AND PROFILES AS PRESCRIBED BY THE INTERSTATE COMMERCE COMMISSION. 1914.

UNITED STATES STEEL CORPORATION. 11th Annual Report, 1912.

U. S. WAR DEPARTMENT. Report of the Governor of Porto Rico. 1913.

UTAH. STATE ENGINEER. 7th, 8th, Biennial Report, 1909-10, 1911-12.

WESTINGHOUSE AIR BRAKE Co. Instruction Pamphlet nos. 5027, 5028, 5030, 5032, 1907.

WYOMING. GEOLOGIST'S OFFICE. Bulletin nos. 5-7, Ser. B. 1913-14.

GIFT OF ATLANTIC DEEPER WATERWAYS ASSOCIATION

Address of Hon. J. H. Moore, before the Rivers and Harbors Congress, December 9, 1909.

ATLANTIC COASTAL AND WESTERN WATERWAYS. Address of J. H. Moore, November 17, 1909.

ATLANTIC INTRA-COASTAL WATERWAY. 1911.

EASTERN WATERWAYS NEEDS. Address of J. H. Moore, November 18, 1913.

FREIGHT RATE FAVORITISM, THE MOTHER OF MONOPOLIES. Speech of Hon. Wm. J. Gaynor, October 18, 1911.

ISLAND ROUTE SOUTH TO NORFOLK. Paper read by Anthony Huggins, November 18, 1909.

INLAND WATERWAYS, STORY OF THE ATLANTIC COASTAL PROJECT AND ITS DEVELOPMENT. Address by J. H. Moore, October 18, 1911.

INLAND WATERWAYS PROGRESS. 5th annual address of J. H. Moore, September 4, 1912.

PROGRESS OF THE CAPE COD CANAL. Speech of J. W. Miller, October 19, 1911.

NAVAL VIEW OF INLAND WATERWAYS AT HOME AND ABROAD. Paper read by C. S. Spetty, November 18, 1909.

RELATION OF RAILWAYS TO CANALS. Paper read by J. F. Stevens, November 17, 1908.

REPORT OF THE COMMITTEE ON TRAFFIC OF THE PROPOSED INTRA-COASTAL CANAL CONNECTING NEW YORK AND DELAWARE BAYS. 1911.

RHODE ISLAND WATERWAYS AND THEIR OUTLET. Paper read by A. J. Pothier, November 18, 1909.

WASHINGTON AND WATERWAYS. Address of J. H. Moore, October 19, 1909.

GIFT OF C. W. RICE

GRAPHICAL SOLUTION OF HYDRAULIC PROBLEMS, F. C. Coffin. New York, 1897.

ALTERNATING CURRENT WIRING AND DISTRIBUTION, W. LeRoy Emmet. New York, 1891.

ELECTRICITY AND MAGNETISM, Fleming Jenkin. ed. 8. London, 1885.

PRACTICAL GAS ENGINEER, E. W. Longanecker. 1901.

ELEMENTARY LESSONS ON SOUND, W. H. Stone. London, 1879.

ELEMENTARY LESSONS IN ELECTRICITY AND MAGNETISM, S. P. Thompson. London, 1887.

TUNNELS AND TERMINALS IN GREATER NEW YORK.

GIFT OF BUREAU OF RAILWAY ECONOMICS, WASHINGTON, D. C.

ADDRESSES OF WILLIAM C. BROWN at dinner given by The Boston Chamber of Commerce, June 12, 1913; Chamber of Commerce of the United States, Dec. 8, 1913; The Iowa Society of New York, March 4, 1910; The Railway Business Association, Nov. 10, 1909; Railway Young Men's Christian Association of Columbus, Ohio, Feb. 4, 1911; The Rochester Chamber of Commerce, March 18, 1910.

ADDRESS TO THE ANNUAL CONVENTION OF THE AMERICAN ASSOCIATION OF GENERAL PASSENGER AND TICKET AGENTS, Howard Elliott. Sept. 16, 1914.

AGRICULTURAL AND INDUSTRIAL PROGRESS DEPENDS UPON PROSPEROUS RAILROADS. An address, by F. Harrison, Feb. 24, 1914.

CONCERN OF THE RAILROAD EMPLOYEES IN THE EXISTING RAILROAD SITUATION. ed. 2. Aug. 1910.

CONNECTICUT AND THE NEW HAVEN ROAD. Address to the Chamber of Commerce of New Haven by H. Elliott, Nov. 19, 1913.

FUTURE OF THE SOUTHERN RAILWAY IN NORTH CAROLINA. An address by F. Harrison, Sept. 8, 1914.

HEARINGS BEFORE A SUB-COMMITTEE OF THE COMMITTEE ON NAVAL AFFAIRS UNITED STATES SENATE. July 27, 1914.

A LIVING RATE FOR THE RAILROADS, M. W. Gaines.

LUMBER INDUSTRY IN RELATION TO THE SOUTH. EFFICIENCY IN LUMBERING AND IN RAILROADING. Address by W. W. Finley, March 1, 1911.

A NATION'S NEGLECT, M. A. Dow.

NEWSPAPERS AND RAILROADS AS FACTORS IN SOUTHERN DEVELOPMENT. An address by F. Harrison, July 7, 1914.

PREJUDICE AGAINST THE RAILWAYS. An address by F. Harrison, Apr. 30, 1914.

RAILROAD ORGANIZATION. Address by R. V. Taylor, Aug. 20, 1914.

RAILROADS AND HUMAN NATURE. Address by L. L. Lee, May 19, 1914.

RAILROADS AND PUBLIC RELATIONS. Address by J. H. Baumgartner, June 26, 1913.

RELATION OF THE RAILWAY TO COMMUNITY AND STATE-WIDE ADVERTISING. Address by H. Elliott, Nov. 29, 1910.

SOUTHERN RAILWAY AS A FACTOR IN THE PROGRESS OF GEORGIA. Address by F. Harrison, Apr. 22, 1914.

SOUTHERN RAILWAY BELONGS TO THE PEOPLE OF THE SOUTH. Address by F. Harrison, Jan. 20, 1914.

SOUTHERN RAILWAY COMPANY AND ITS EMPLOYEES AS AFFECTED BY THE EUROPEAN WAR. Address by F. Harrison, Sept. 7, 1914.

STOP, LOOK, LISTEN, F. V. Whiting.

SURGEON AND THE RAILROAD. Address by F. Harrison, June 19, 1914.

TESTIMONY OF SAMUEL REA, PRESIDENT OF THE PENNSYLVANIA RAILROAD COMPANY, BEFORE THE INTERSTATE COMMERCE COMMISSION IN THE MATTER OF INCREASED FREIGHT RATES.

OFFICERS AND COUNCIL

President

AMBROSE SWASEY, PAST-PRESIDENT OF THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS, DONOR OF THE INITIAL GIFT TO THE ENGINEERING FOUNDATION, INAUGURATED BY THE UNITED ENGINEERING SOCIETY FOR THE FURTHERANCE OF RESEARCH IN SCIENCE AND ENGINEERING, OR FOR THE ADVANCEMENT IN ANY OTHER MANNER OF THE PROFESSION OF ENGINEERING AND THE GOOD OF MANKIND.

THE HISTORY OF THE SOCIETY

IN 1914 the Society completed one-third of a century of its organic life. The Council requested the Honorary Secretary who had served as Secretary during twenty-three years of that period to prepare a record of what the Society had accomplished in that time.

This history is about ready to go to press. It will contain over 200 pages in the standard form of the Transactions of the Society and will be illustrated by over 50 photogravures, portraits of the Presidents and illustrations of the buildings and headquarters which the Society has occupied. It seeks to give the personal touch which the mere summation of the minutes of the Society cannot supply. Its chapters include, among other subjects:

- The Preliminary Steps of Organization
- Some Principles of Society Philosophy
- Some Early Members of the Society
- Some Notable Papers Read Before the Society
- Meetings of the Society and What Has Made Them Memorable
- Internal or Office Activities of the Society
- The Headquarters
- The European Trips
- Professional Standards
- Professional Sections, Groups and Student Branches

The history will be sold on a subscription basis at \$5.00 per volume in standard binding. Those desiring copies of the history will please communicate with the Secretary of the Society. Members may place their orders and have the volume charged to their accounts.

THE ENGINEERING FOUNDATION

ON Wednesday evening, January 27, 1915, was held in the auditorium of the Engineering Societies Building the inaugural exercises of The Engineering Foundation, established by the United Engineering Society. The initial gift to the Foundation of \$200,000, made by Ambrose Swasey, Past-President of The American Society of Mechanical Engineers, was formally accepted at this time. So far as known this is the first instance of a foundation devoted to engineering purposes. This meeting constituted also an appropriate tribute to the generous gift made to the Foundation and gave opportunity for expression of the satisfaction and approval which are felt by engineers everywhere at the establishment of a means of promoting the good of mankind through the work of the engineer along the broadest lines.

Gano Dunn, President of the United Engineering Society and Past-President of the American Institute of Electrical Engineers, acted as presiding officer, and on the platform were seated representatives of the three societies constituting the United Engineering Society, and of the American Society of Civil Engineers. Members of the four societies and many other friends interested in the profession composed the audience.

The first address of the evening was made by Gano Dunn, who reviewed the history of the Engineering Societies Building, the purpose of the United Engineering Society, and the formation of The Engineering Foundation.

ADDRESS BY GANO DUNN

Mr. Dunn said that the United Engineering Society is a creation for the purpose of enabling three of the great engineering societies, The American Society of Mechanical Engineers, the American Institute of Mining Engineers and the American Institute of Electrical Engineers, to do jointly more than they could do separately. It is a corporation which holds in trust the property on which the Engineering Societies Building is located, the building itself, and its contents. The property and its contents were con-

tributed by the founder societies, and the building by Mr. Andrew Carnegie. The interesting fact was pointed out that the celebration of the inauguration of The Engineering Foundation occurs almost exactly ten years from the date of the first meeting of the United Engineering Society, so that this occasion is partly a decennial. It is to be hoped that in the next ten years as much fruit will be born of the Foundation as the United Engineering Society has produced during the past ten years. The charter of the United Engineering Society contained among the other paragraphs describing its powers the following: "To take real and personal property by grant, devise or bequest, and use, maintain, occupy, lease, mortgage and convey the same." It was in the minds of the men who drafted this document that the time would come when the usefulness of the United Engineering Society would extend far beyond a corporation for owning and administering the building. But, said the speaker, ten years went by before that provision was made use of, and tonight we are together because a distinguished engineer, a man of marked intellectual power, a man of marked personality, has felt in his heart that he wanted to do what would most benefit not only the engineering profession but mankind, and believed that through the agency of the United Engineering Society it could be done.

We have foundations of many kinds,—for philanthropy, for civic betterment; foundations for many noble purposes seem to characterize American public life. But as yet we have to hear of a foundation in engineering. At last our turn has come, at last the human element is recognized among engineers in benefaction, and at last engineering is included among those human activities which are felt to be sufficiently important to promote.

The speaker explained that when the trustees of the United Engineering Society came to consider all the possible objects and uses to which a foundation could be put, they felt it could be best administered if in the hands of a responsible and distinguished board, separate from their own, with entire freedom

as to the expenditure of their resources. It was felt further that the work could never be successful or representative of the whole field of engineering if its roots were in only the three national engineering societies which constitute the United Engineering Society. Without the coöperation of the American Society of Civil Engineers, he said, "the pioneer society that we and all engineers have looked up to with honor and respect; the society from which we have taken our standards of conduct, the society whose numbers are more advanced generally in years, the society whose name we as engineers have loved to conjure with when we have been speaking with pride of the accomplishments of engineers—that society, we felt, must take part in the work of the United Engineering Society, or the work of the Foundation could not be expected to be successful. The structure of the Engineering Foundation, therefore, was so arranged that it should be managed by a Board of eleven members, of which the President of the United Engineering Society should be ex-officio one, two members from each of the founder societies, two from the American Society of Civil Engineers, and two from the world at large. In this latter provision the trustees hoped to introduce into the Foundation an outside element and a point of view that would forever save the Board from becoming narrow, and would likewise inspire new ideas." The speaker said that in his opinion they never did so wisely as when they called upon the world in general to share with them in administering this great trust.

Mr. Dunn said that in proposing this structure to our sister society and inviting them to share in the management of the trust, a letter of acceptance was received which the trustees felt insured that the future of The Engineering Foundation would be a brilliant one. After consideration on the part of its officers and its official board of direction, the American Society of Civil Engineers replied as follows:

I have the honor to state that your letter of January 5, 1915, was presented to the Board of Direction of this Society, together with the Amendments to the Charter and By-Laws of the United Engineering Society, which provide for The Engineering Foundation, and that the action of the undersigned in the matter up to that date was approved.

I am instructed further to say that the American Society of Civil Engineers is very glad to become one of the four societies to be represented on the Board in whose hands the administration of The Engineering Foundation is to be placed.

I am instructed also to express to you, and through you to all who have been interested in this matter, and especially to the donor of the present endowment, the appreciation of the Board of Direction of the American Society of Civil Engineers of the courtesy which has been extended to the Society in giving it the opportunity to participate in this movement.

Yours very truly,

(Signed) CHAS. WARREN HUNT, *Secretary*.

In conclusion Mr. Dunn said:

"This structure was created at this time because of the

urging of the donor, whose name I have not mentioned, but whose personality I have indicated, and now that I have described it, I should like to announce what he has done, and who he is. In doing this, I again wish to comply with his request that his part be made as small as possible, and I must say that this on my part, is a perfunctory compliance, because, while he undoubtedly wishes it so, we can never forget how large is the part he has played not only in giving this endowment, but in initiating and creating the structure that undoubtedly will be the receptacle of many future endowments, and the center and source of much important work in the future."

This is the letter:

DEAR PROFESSOR HUTTON: I am pleased to acknowledge receipt of yours of the 20th instant, also copy of the minutes of the Board of Trustees of November 19, and I appreciate the courtesy of the Board in submitting them to me before final approval.

The name adopted, "The Engineering Foundation," is ideal, and the plan of organization and administration, as given in the minutes, is along the broadest lines and most admirable in every respect. I have no suggestions or recommendations to offer.

As soon as I am advised that the plan of organization of The Engineering Foundation submitted has become the law of The United Engineering Society, I will be pleased to transmit to the officer designated by the Society, the two hundred thousand dollars (\$200,000) which constitutes my gift to the Society for The Engineering Foundation; the income only of which is to be used for the purposes of the Foundation.

As to the date of the general meeting when the plan of the Foundation is to be made public, if agreeable to the Board, it seems to me it would be well to have it some time during the last week in January.

I want the members of the Board to know how much I appreciate the interest they have manifested in working out the problems relative to the Foundation, and the pleasure it has given me to be associated with them in their splendid undertaking.

With all best wishes,

Very truly yours,
(Signed) AMBROSE SWASEY.

REMARKS BY AMBROSE SWASEY

Mr. Swasey was then called upon by the Chairman and very briefly expressed his appreciation of the cordial manner in which the announcement had been received. He believed that the meeting was also evidence of the appreciation felt of what had been accomplished by the United Engineering Society and the work which they had done in planning and bringing about this Foundation. It is a very simple matter to throw a few shovelful of coal under the boiler, he said. We must have fuel if we would have power. But to the engineers who designed the boiler and the engine, and who so proportioned them and so correlated them that the products of combustion can be used to greater advantage than ever before for the benefit of mankind, the greater credit belongs.

ADDRESS BY ROBERT W. HUNT

Robert W. Hunt, Past-President of the American Institute of Mining Engineers, paid a personal tribute to Mr. Swasey, as a lifelong friend, and said that it is

one of the few certainties of this world that the greatest earthly happiness comes to those who have made others happy. The United Engineering Society, which will administer this Foundation "to develop, direct and conserve the forces of nature for the benefit and uplift of mankind through the instrumentality of the engineer;" was made possible by the generosity of one man, Andrew Carnegie. He wisely surrounded his gift made in recognition of the profession and the men who had made possible his own financial success, with conditions which required efforts and contributions from others, and also, as became a true humanitarian, did not make the institution a personal one. As a result engineers in every department of the profession, as well as all believers in engineering, have united in making the proposition successful, entirely ignoring self.

This Foundation is the conception of one man who does not seek individual aggrandizement, but rather through his own munificence to create a base upon which others can unite with him in building a structure which will benefit all humanity. This structure will not be his nor any other man's, but to each one who may hereafter add to its growth and usefulness will be given the happiness incident to helping to uplift mankind. This is no new rôle to Mr. Swasey, to whom all human beings, whether they have the yellow skin of the Far East or are the laboring boys and men of his own country, are fellow-mortals. While he built telescopes to comprehend in part the incomprehensible universe, his love for and his desire to serve his fellow men has grown and has manifested itself in many ways.

Mr. Hunt related an incident of Mr. Swasey's successful fight for the new post office building in Cleveland, which was finally built, as a result of his efforts, of granite instead of limestone. This was but an instance of Mr. Swasey's many unselfish efforts for public welfare. Many of his works of benefaction were known only to a few. He spoke also of his lifelong friendship with Mr. Swasey and said that in the starting of this project Mr. Swasey was only opening the way and making it practical for others to give.

ADDRESS BY HENRY S. PRITCHETT

Dr. Henry S. Pritchett, President of the Carnegie Foundation for the Advancement of Teaching, spoke upon the significance of the gift and its meaning for engineering science and civilization. Great numbers of research institutes already exist in Europe and America, but never has such an agency for research been placed in the hands of a group of engineering societies. The word research has become almost a shibboleth in university circles; but it must be confessed that a great proportion of this is the imitation, not the reality. In the sense in which it is used in this Founda-

tion, he thought, it means the attempt to formulate and solve those problems of science which touch most directly the comfort, the happiness and the progress of the nation and of the world. In this process it requires quite as high an order of ability to formulate the problem clearly as to solve it.

"Research considered as a process of scientific thinking and discovery is not a task to be set before the immature and the untrained. It is quite true that the best training for research may not always lie in university halls. A long roll of illustrious men whose names the world cherishes found their way to the solution of the great problems of science and of industry by other paths than the university. This means simply that they became thinkers in their own way.

"The process of research, therefore, as one may expect it to be carried forward by such an agency as this, involves first the clear formulation of problems, and then the attack upon the problem by all the avenues and by all the agencies of science; and this process, it may well be assumed, will be successfully carried out only by those men who have learned to think, who are familiar already with the present state of science, and who—using this as a basis—push forward the boundaries of our knowledge into new fields. True research implies clear thinking, minute knowledge of the field of science, and patient endeavor.

"The development of such a research agency by the great engineering societies, through a fund entrusted to them, has, to my thinking, far reaching significance, first, for engineers themselves; secondly, for research; and in the third place, for the public, the great body of citizens.

"So far as engineers themselves are concerned, the offer and acceptance of this foundation signalizes the fact that engineering in America is to-day a profession, not a business. For two centuries and more the civilized nations have recognized three great professions—that of the law, of medicine and of the clergy. Only within our generation has engineering been admitted to the fellowship of this group; and it has come because the world now recognizes that the man who serves in the field of applied science, if he serve in the right spirit, gives a part of his energy to the service of the public. It is in just this respect that business differs from a profession. Physician and lawyer and clergyman accept pay, but in each of these professions it is clearly recognized that the service must not be governed by the pay, that a large part of the energy of the profession must be given to the service of the common good, that members of a profession occupy a quasi-public relation. Only when the men of a calling attain this sense of professional consciousness can the calling pass from that of a business to that of a profession. The members of a vocation who take upon themselves the responsibility for the direction and encouragement of scientific research have risen out of the business of engineering into the profession of engineering.

"With regard to research it may be said that, while engineering research in its essence partakes of the nature of all research, it undertakes to formulate an answer to certain questions which are not likely to be dealt with successfully elsewhere. Ever since universities and institutes for research have existed there has gone on the discussion between what is called theory and what is called practice. As Professor

Pupin has well put it. 'It is the practice which formulates the question; theory seeks to answer it.'

"It is the man in the practice who formulates the question. It is the scientist who finds the answer.

"The criticism of university research has been that theory and practice, the man who formulates and the man who solves, have not always been happily related. In a research agency conducted by associations of engineers there ought to be the most fortunate alliance of theory and practice. Here, the practitioner who questions and the man who seeks to solve, the man who formulates and the man who delves ought to find their closest association. And it will be interesting to observe how, under such auspices, theory and practice will learn to go hand in hand.

"To the public the foundation of such a research agency in the field of applied science may well mean the inauguration of a series of studies having the greatest significance for public well-being and for public needs. The most striking illustration of such a result has been already given in the history of a small research laboratory of applied science, started in the technical school, at Charlottenburg, some forty years ago. The effort arose out of the questions formulated and laid before the scientific staff of the technical school by the men of the steel industry; and out of the solutions of these questions the steel industry of Germany grew. Gradually the inquiry arose, why should there not be an institute of engineering research to which any citizen engaged in the industries may bring his problems? to whose laboratories may be brought not alone the questions relating to the manufacture of steel, but those relating to the chemical industry, textile industry, electrical manufacturing and industries of every sort, in a word, all the questions which to-day in the manufacturing establishments of a great nation are constantly being asked?

"Out of the little research laboratory at Charlottenburg have grown the great testing laboratories (Versuchsanstalt) covering many acres and offering themselves freely to the solution of every technical question that the industries in Germany can present. Any company engaged in the industries may bring its problems here. Any experts may come in and take part in the study, all the literature on the subject is made available, and under the combined efforts of the expert of the government laboratory and the experts of the industry a solution is generally found.

"The process is illustrated by the story which a paper manufacturer in Berlin told to me some years ago. His company manufactured wood pulp from the forest of a certain region. A change was made and their wood supply was drawn from another region. The formulae they had hitherto used no longer sufficed, and despite every effort of their own no solution had been found. Financial ruin stared the company in the face. The problem was carried up to the government laboratories of engineering research. At the end of two months all difficulties had vanished and prosperity returned to the manufacturer.

"Dr. Martens, the director of the research institute at Grosslichterfelde, told me that the complete and orderly collection of scientific literature and of scattered scientific solutions in research made available at Grosslichterfelde was one of the great factors in the success of the research establishment. 'Four times out of five,' said he, 'when a manufacturer brings us a problem we find that it has already been

solved somewhere in the world by somebody, but by someone who generally used the solution in a different connection. Our greatest service is to place at the disposal of the inquirer the entire literature of his subject, and in this he will generally find a solution of his question already made.'

"Who can tell but that this modest agency for research, under the direction of the great engineering societies of America, may develop in due course into a national establishment to which any man in the industries may bring his problem with full hope of solution?

"We found here to-night an agency for human uplift and human development. It is founded not in brick and mortar but in the living engineers of these great engineering societies, which shall go on from decade to decade and from generation to generation. If our civilization endures, this association of engineers will develop with the ages. They will never die. And in their hands this agency of research will also be immortal, serving humanity from century to century and from age to age.

"It has been founded by an engineer at once wise and modest. To have founded such an immortal agency for human endeavor is to become oneself a partaker in immortality."

REMARKS BY CHARLES McDONALD

Following the address by Mr. Hunt, the Chairman called upon Mr. Charles McDonald, Past-President of the American Society of Civil Engineers, saying that if The Engineering Foundation had no other virtue than to bring into closer unity the four great engineering societies, it would have accomplished results of greatest value.

In response Mr. McDonald said that the American Society of Civil Engineers welcomed the efforts to be made through this gracious gift to The Engineering Foundation. His society would be glad to cooperate in working for the general good of the profession. No matter what organization he was representing, he wished to be considered at this time as a member broadly of the whole profession.

REMARKS BY ALEX. C. HUMPHREYS

Dr. Alex. C. Humphreys, Past-President of The American Society of Mechanical Engineers, then formally accepted Mr. Swasey's gift in behalf of the Board of Trustees of the United Engineering Society. He quoted the by-law of the Society which covered the administration of such a fund and which reads as follows:

The Engineering Foundation Board shall have discretionary power under the By-Laws in the disposition of the funds received by it.

The Board may use any part of its funds and in any manner, which it deems proper for the furtherance of research in Science and Engineering, or for the advancement in any other manner of the Profession of Engineering and for the good of Mankind.

The Board may, by publication or public lectures or by other means, in its discretion, make known to the world the results of its undertakings.

This By-Law, he said, had been written in an effort to interpret Mr. Swasey's broad-minded and self-effacing intentions.

The acceptance of the fund, he said, meant the acceptance of a grave responsibility, which would, he believed, be met with the full determination on the part of the representatives, present and future, of the four societies to administer this fund and additional contributions in the interest of the larger needs of mankind. He hoped that the Foundation in its activities would always stand for the truth, the whole truth and nothing but the truth.

AMBROSE SWASEY

Donor of the Initial Gift to the Engineering Foundation

Ambrose Swasey is widely known as a member of the firm of Warner & Swasey of Cleveland, Ohio, prominent machine tool builders and the foremost builders of telescopes in the world. Among the instruments which they have designed are the famous Lick, Yerkes, and United States Naval Observatory telescopes, as well as the great 72-inch reflecting telescope for the Canadian Government, which is now under construction. Mr. Swasey is known also, in addition to his engineering achievements, for his practical efforts towards scientific education and the advancement of the profession. His gift for the establishment of The Engineering Foundation is in line with these undertakings, which may be destined to outlast his fame as an engineer. Mr. Swasey gave the handsome observatory to Denison University at Granville, Ohio, and the science building for the University of Nanking and the Young Men's Christian Association Building for the Canton Christian College now being erected in China, were made possible through his gifts. He has also, as president of the Warner & Swasey Company, interested himself earnestly in the establishment and conduct of its school of apprentices, and indeed the weight of his influence is to be found in every project tending to the development and encouragement of the human element, helping men to help themselves.

Dr. John A. Brashear, a life-long friend of Mr. Swasey, gave the following account of Mr. Swasey's life in an article which appeared in *Cassier's Magazine* for March 1897. The whole article, which cannot here be reproduced because of lack of space, is well worth reading as the tribute of one eminent astronomer to another.

"Ambrose Swasey was born in Exeter, N. H., his ancestors being among the early settlers of New England, coming to America in 1638. He received his education in the 'Little Red School House' of the district, and his after life has shown that the seed sown by the old schoolmaster fell upon good ground. At the age of eighteen he entered upon the machinist's

trade in Exeter, and in 1870, in company with his present partner, Mr. Worcester R. Warner, he left the granite hills of his native State to go into the employ of the Pratt & Whitney Company, at Hartford, Conn. His energy and ability soon became manifest to his new employers, and his aptness in the solution of mechanical problems was so thoroughly appreciated, that the remark, 'Send it up to Swasey,' was a common one with them.

"While in charge of the gearing department, he invented and perfected the epicycloidal milling machine for producing the true theoretical curves of the teeth of gears, and a few years later he made another advance step in the solution of that difficult problem, inventing an entirely new process for generating and cutting spur gears, which proved a practical solution of the very important theory of the interchange system of gearing. In 1880, Mr. Swasey resigned his position with the Pratt & Whitney Company and, together with his present partner, established in Cleveland, O., the business which has since grown to such large proportions. Mr. Swasey's inventive and mechanical genius has emphatically manifested itself in the design and construction of the fine machine tools and astronomical instruments made by his firm.

"It seems a most fortunate circumstance that these two men, Ambrose Swasey and Worcester R. Warner, should have associated themselves together as partners, for although the making of astronomical instruments was not in their original scheme when starting the business of machine construction, Mr. Warner's taste for astronomy, and his interest in the appliances used by astronomers, combined with Mr. Swasey's love for artistic design, and his ability as a mechanical engineer, naturally led them to take hold of the questions pertaining to such instruments.

"In recent years observatories and instruments had increased to such dimensions in America that most intricate problems, requiring the highest engineering skill, were demanding solution. The largest refracting telescopes constructed previous to 1880 were the 26-inch telescope of the United States Naval Observatory, at Washington, D. C., the 27-inch of the University of Vienna, Austria, and the 30-inch instrument of the Pulkova Observatory, Russia; but the Lick telescope, as projected, was to have nearly half as much more light-gathering power than any refractor that had hitherto been constructed, and the difficulties of mounting such an immense instrument are enormously greater than those attending the construction of a smaller one.

"In 1886 the Lick trustees invited four firms to submit designs for the 36-inch telescope, which was to be the largest and most powerful ever constructed. Two of the competing firms were from abroad and two from the United States. . . .

"The competing designs for this great telescope were sent to the Lick trustees in San Francisco, and after careful consideration the plans submitted by Messrs. Warner & Swasey were accepted, and they were awarded the contract, although their price was the highest. The design of this important instrument was carefully studied in every detail, and the highest standard of excellence was maintained throughout. It was finally erected on Mount Hamilton, in California, during the winter of 1887 and 1888 under Mr. Swasey's personal supervision."

This instrument was very naturally subjected to much criticism, but it stood all the tests and when the Government desired to reconstruct the Naval Observatory at Washington in 1890, the Warner & Swasey Company were given the contract for the 26-inch telescope; and they were also later entrusted with the task of making the 40-inch telescope, and also the 90-foot dome and the 75-foot elevating floor, for the Yerkes Observatory, Williams Bay, Wis.

The manufacture of meridian circles, transits and other astronomical instruments of extreme accuracy and precision has formed a large part of the firm's work, and in the designing of all these instruments Mr. Swasey has taken an important part. For graduating the fine circles of these delicate instruments, it was necessary to have a circular dividing engine, and as there was no instrument in the country of sufficient accuracy, the problem was taken up of designing and perfecting such an engine which, when completed, was capable of dividing circles automatically up to 40 inches in diameter with an error of less than one second of an arc, probably the most accurate circular dividing engine ever constructed.

Mr. Swasey is the inventor of a number of instruments used by the Government in its coast defense, including several improvements in the construction of range finders.

Many honors have come to Mr. Swasey for his work and achievements. He is a past-president of the Society, a member of the Institution of Mechanical Engineers of Great Britain and of the British Astronomical Society, he is a Fellow of the Royal Astronomical Society, is past-president of the Cleveland Engineering Society, and, in 1900, received from the French Government the decoration of The Legion of Honor for his achievements in the design and construction of astronomical instruments. He was a member of the Jury of Awards of the Nashville, the Pan-American and the St. Louis Expositions and Vice-President of the Jury of Awards of the Jamestown Exposition. In 1905 he served as president of the Cleveland Chamber of Commerce, and the same year the degree of Doctor of Engineering was conferred upon him by Case School of Applied Science. Mr. Swasey was married October 24, 1871, to Lavina D., daughter of David and Sarah Ann (Dearborn) Marston, and he and Mrs. Swasey had traveled exten-

sively up to the time of Mrs. Swasey's death early in the year of 1913.

TESTIMONIAL DINNER TO AMBROSE SWASEY

The President and Trustees of the United Engineering Society tendered a testimonial dinner to Mr. Ambrose Swasey, Past-President of The American Society of Mechanical Engineers, at the University Club, Tuesday evening, January 26, 1915.

There were present the members elect of the Board of Trustees of the United Engineering Society, the presidents and secretaries of the four national engineering societies and the Engineers' Club, the speakers at the inauguration of the Foundation on Wednesday, a group of other friends in the several societies who had been conferring with Mr. Swasey in the development of the Foundation, and the benefactors of the founder societies.

Impromptu addresses were made by John Hays Hammond, E. D. Adams, Charles F. Scott, and T. A. Rickard of London, member of the Iron and Steel Institute, editor of the Mining Review of London and the Mining and Scientific Press of San Francisco. Mr. Rickard commented on the status of the progress of the professional engineer in relation to the status of members of the other professions, of law, etc. Dr. H. S. Pritchett also spoke of the enduring features of a foundation administered by an engineering society which would go on from generation to generation and from century to century. Dr. M. I. Pupin spoke of the opportunities of useful service which this Foundation could render. In conclusion, Mr. Swasey himself made a few remarks, saying that his contribution was only the beginning and that it was his hope that engineers generally would make further contributions. The final greeting to Mr. Swasey, all members of the dinner rising to their feet, was a vow similar to that made by the signers of the Declaration of Independence: "For the support of this Declaration, . . . we mutually pledge to each other, our lives, our fortunes and our sacred honor."

COMMENTS ON THE ENGINEERING FOUNDATION

As the first endowment to be devoted to the advancement of engineering, much interest has been aroused as to the purposes for which The Engineering Foundation will be expended. Mr. Swasey in making the first gift to the Foundation, wisely and characteristically made no stipulation as to the method of its application, and there has as yet been no announcement from the Board which will administer the fund.

A number of members of the Society and others interested in engineering have been asked to express their opinion upon the value of this Foundation and to make any suggestions they may have as to how it may best

be applied. Quotations from their replies are given herewith. None of these embody any official statement, but will be interesting nevertheless as representing various viewpoints.

The replies follow:

My opinion of the significance of the Foundation is well expressed in a wire which I have formulated to send to Mr. Swasey on the morning of Wednesday, the twenty-seventh. It is as follows:

"My dear Mr. Swasey: This is a significant day. By your thoughtful and generous action, it introduces a process whereby new truth will be revealed, engineering practice will be improved, industry will be stimulated and the progress of mankind advanced. Pray accept from me, a humble worker in the ranks, expressions of sincere appreciation and renewed assurances of personal admiration and esteem. May God bless you and give you satisfaction and joy in the foundation you have created."—W. F. M. Goss.

The Engineering Foundation established by the United Engineering Society, to which Mr. Ambrose Swasey, Past-President of The American Society of Mechanical Engineers, is the first contributor, marks a new point of departure in the advance of the Engineering Profession.

Not the least important feature of this very important undertaking is the enlistment of the interest of the four national societies of Civil, Mining, Mechanical and Electrical Engineers in a common cause for the advancement of the Profession.

What Mr. Swasey has done others may be encouraged to do when it has been shown that The Engineering Foundation is being administered upon broad principles and the results obtained are of value and are given free to the Engineering Profession of the world. The success and the power for good of this great undertaking devolves upon The Engineering Foundation Board.—JESSE M. SMITH.

I am delighted to know of the inauguration of The Engineering Foundation and I congratulate the profession not only on the possession of such an aid for the advancement of the arts and sciences connected with engineering but on having in its ranks one who is willing to aid in the work of benefiting mankind. I feel that such a foundation would have a wide field of usefulness in making grants to aid in investigations which are being made or which should be made. A little aid at the right time may help many to finish work which would remain unfinished without this. I am sure that great good will result from The Engineering Foundations.—ARTHUR M. GREENE, JR.

A natural use for the income of such a fund would be the carrying on of researches along mechanical lines through committees of the Society, in such a way as to add to the fund of engineering knowledge. As an illustration, such work as Mr. F. A. Halsey is proposing to do, when financial backing can be secured, in connection with the testing of worm drives and the action of worm wheel and spiral teeth, would seem to come directly in the class mentioned.

Also, such work as is being done by the various committees of the Society; for example, our Committee on Screw Thread Limits and Tolerances has suggestions in mind as to methods of gaging and measuring screws, so as to determine simultaneously the errors of lead and diameter. If funds were available to produce such gages and actually make a trial of them, more tangible results would follow than are possible at the present time.

It goes without saying that there would have to be careful guarding of the use of such funds as they would easily be dissipated in useless experiments and for side issues which would not materially advance the arts and sciences connected with engineering.—LUTHER D. BURLINGAME.

In my opinion the most important matter now required to advance the science of engineering, to place it on a high

plane as a profession, and to facilitate the work of research in engineering, is the maintenance and publication at frequent intervals of a catalogue with abstracts of all engineering literature. This collection of abstracts should be similar to the abstracts made and published in the publication known as *Chemical Abstracts*; it should be so well indexed and furnished with cross references that a man interested in any one subject would quickly and accurately secure an abstract of all the articles that appear on that subject. It should be so complete that a patent attorney might use it for looking up the state of the art and rest assured that he would miss nothing within the period covered by the publication. It should be checked up at the end of every year with all the various indexes published, in order that it might be found that nothing had been missed. The abstracts should be made by technically trained persons and not by trained librarians.

They should be sufficiently comprehensive to give a man a very accurate idea of what the article contains, so that he can determine, for himself, whether or not it was worth his while to read the whole article, but should avoid all repetitions and unnecessary language. It should be so accurate as to remain the standard for this kind of work, and it should cover publications in the language of every country likely to interest engineers. It should be so practical that no engineer, who pretends to keep in touch with the progress of his profession, could afford to neglect to read it as promptly as it appeared.

In case such an index could be maintained it would be entirely unique among abstracts of this kind and would be a boon to the profession of engineering whose value it is impossible to over-estimate. The work should be done, however, in cooperation with other institutions that are making abstracts, in order that such collaboration might lessen the labor of all.—BRADLEY STOUGHTON.

My judgment would be to utilize practically all of the income in paying the salary of a director, with enough off to provide for a stenographer and a minimum of other expense, such as printing.

There are a thousand different minor researches that might be carried on for the advancement of the arts and sciences connected with engineering and which perhaps would bring about some slight benefit to mankind, but I believe the biggest return that could be obtained for the amount at present available would be to put in charge of the Foundation a man of sufficient calibre to bring his good offices to bear on the coordination of such engineering research as is now being carried on and further to really find out about and keep in touch with what is now being done.

The standing of the Foundation in the community is going to be very largely determined by its early activities and it seems to me that the best impression on the community would be made by one strong man.—M. L. COOKE.

I cannot speak too highly of the generosity, public spirit, and devotion to the profession of that splendid man, Ambrose Swasey, through whose munificence the creation of The Engineering Foundation is due. As to the direction in which this fund could best be devoted to benefit the engineering profession and the human race, in my opinion the greatest need of the engineering profession today is neither more literature nor more scientific experiments to accumulate data, but a better appreciation by the public, which employs engineers, of what the engineer can do, coupled with a clearer understanding of the proper method to be adopted in engaging an engineer to undertake a particular piece of work.

Few engineers in active life who are in close touch with present day conditions, have the leisure to undertake a broad investigation of this sort and study out possible plans of action. An organization such as The Engineering Foundation, however, could employ and pay an engineer, and a competent staff, if necessary, to investigate this whole matter, and make it his business to find a solution as he would find the solution for an engineering problem.

It will, of course, be admitted that the ideal of placing an engineer perfectly equipped for his task in charge of every important piece of engineering work in the country is an ideal impossible of attainment. When one is aware, however, of the many million dollars which are spent in ill-advised and unwise work every year by cities and towns and private corporations, he cannot but feel that if the work were done by better engineers, far better results would be secured. Certainly no other subject compares with this in the interest it is now arousing in the engineering profession everywhere. All sorts of proposals are made and discussed by individual engineers and by engineering societies. An authoritative investigation, made by an organization representing all the national engineering societies, would be of value to every member of the engineering profession and could hardly fail to place the profession on a better footing before the public.—CHARLES WHITTING BAKER.

As a civil engineer by profession, I rejoice heartily in the good fortune which has thus come to the united engineering societies, and I feel that my best thought must be given to the request you raise irrespective of publicity. This latter, especially as it is exemplified by the press, does not interest me. I shall be glad, however, to give your association, as I am giving many others, the best counsel available to me, and give it as a silent partner.

I regret very much that I may not be with your company tonight, to indicate by my presence the high regard in which I have long held our friend Swasey, and the delight which his gift to the engineering profession brings to me.—ROBERT S. WOODWARD, *President, Carnegie Institute*.

I am very glad that someone has at last remembered the engineers and I believe a great deal of good can be done with the money already given.—CHARLES S. HOWE, *President, Case School of Applied Science*.

The great question of the hour is a national technical efficiency. I do not mean a mere professional education, such as the efficient bookkeeper receives, but a general training, starting in boyhood and producing a high technical efficiency on the part of the individual that will prove a bulwark to him throughout life and forever relieve him from any anticipation of want through incompetence to earn a living.—GEO. F. KUSZ.

Two great objects of the engineering societies are education and research. Both of these objects are worthy of the expenditure of vast sums of money and of unlimited amounts of energy. The Foundation now established will, I hope, increase in amount and magnitude in the future until the available sum is sufficient to undertake great achievements both in education and in research. The great need of the engineering profession is scientific research conducted with no regard to commercial results and without any influence from commercial organizations. Numerous fields invite study, consideration and investigation, and it is suggested that in the line of research alone the income of the foundation could be employed in such a way as to accomplish much to advance the engineering profession in its place of responsibility and contribute to the welfare and uplift of mankind.—R. C. CARPENTER.

Only two things occur to me: first, I believe a scholarship would be a good thing, similar to the Whitworth scholarship in England, that is restricted to regular apprentices; second, a first class library bureau which would be free to the members of the various societies. Such a library bureau should not only give references to the members on subjects they require but should attempt to coördinate the vast amount of valuable information that is constantly appearing in our technical press. Any number of mistakes occur in engineering work, not because they have not been made before, but because there is no quick method for the men engaged in the work to obtain information.

For instance, I have been up against a problem of drawing cartridge cases and a comprehensive report on this art

would be of the greatest value to me. I do not want references to a large number of periodicals; I would want the subject drawn off from the different sources of information in such a way that the information would be readily useful to me, with perhaps a reference to certain standard works on the subject, which would be found in any reasonably well organized technical library.—H. H. VAUGHAN.

It has always seemed to me unfortunate that there is in this country so little coöperation between those engaged in engineering and in the so-called pure sciences. The distinction should not be between those who do useful things and those who do things the practical applications of which are not obvious, but between those who discover new ways of doing things and those who follow the old ways. It might consequently be desirable for The Engineering Foundation to make plans that would secure coöperation between engineers and mathematicians, physicists, chemists, pathologists and other scientific men.

The British Association makes appropriations to committees which are to a certain extent responsible for work usually done by one or two members. If The Engineering Foundation should adopt this plan, it would be possible to appoint committees representing different aspects of engineering and science.—J. MCK. CATTELL, *Editor of Science*.

No subject of greater importance could demand the attention of The Engineering Foundation than that of an investigation of the subject of building a house for man. This house to have the following points: Extreme durability; no wood whatever, consequently incombustible; specially designed for fewest motions in connection with house-keeping; and specially designed for the elimination of unnecessary fatigue and sickness. Such houses can be built—no two alike—for less money than the individually designed houses of the present time, eliminating the tremendous loss to our country (due to fire), fire insurance, and fire protection. I have been working on this subject for several years in my spare time, and I know that it is a most needed philanthropy—that will at the same time make a good permanent return on the investment. (No great philanthropy will be permanent unless it pays.)—FRANK B. GILBERTH.

COUNCIL NOTES

At a meeting of the Council on January 8, 1915, Prof. Arthur M. Greene, Jr., was appointed to represent the Society on the Conference Committee of the engineering societies, to fill the vacancy caused by the death of Alfred Noble.

The following appointments on Standing Committees were announced by the President: Finance Committee, A. E. Forstall; Committee on Meetings, L. P. Alford, reappointed; Publication Committee, Henry Hess; Membership Committee, George A. Orrok; Library Committee, Jesse M. Smith; House Committee, O. P. Cummings; Research Committee, R. J. S. Pigott; A. M. Greene, Jr.; Public Relations, Spencer Miller; Constitution and By-Laws, James E. Sague. A new feature of appointments may be noted in that there is a member of the Council now on each of the Standing Committees, thus correlating the work of the Society and the Council.

A Committee on Local Sections, E. H. Whitlock, (Chairman, W. F. M. Goss, L. C. Marburg, Walter Rautenstrauch and D. Robert Yarnall, was also appointed.

Appointments on local committees were approved as follows: Boston, C. W. Clark; Cincinnati, George Langen; San Francisco, C. R. Weymouth, chairman, F. H. Varney, vice-chairman, C. T. Hutchinson, secretary, J. T. Whittlesey, H. T. Terwilliger; Atlanta, Earl F. Scott, chairman, Park A. Dallis, secretary, Oscar Elsas, Frank H. Neely, L. W. Robert, Jr.; Minnesota, W. H. Kavanaugh, chairman, E. J. Heinen, vice-chairman, F. W. Rose, secretary.

The Council voted to accept the \$1000 bequest of the late Rear-Admiral Melville, with the understanding that the income be allowed to accumulate until it is sufficient to defray the cost of a die for the medal. This medal is to be awarded annually to such competing member of the Society as shall present the best original paper or thesis on any mechanical subject presented to the Society.

Jesse M. Smith was nominated to the Trustees of the United Engineering Society for election to The Engineering Foundation Board.

The establishment of a student branch at Virginia Polytechnic Institute was approved, and L. S. Randolph appointed Honorary Chairman.

It was voted that a meeting of the Society be held in San Francisco in September 1915 previous to the International Engineering Congress.

An invitation was extended to H. G. Stott to act as chairman of a committee to cooperate with the Standardization Committee of the Manufacturers' Association in the recommendation of flange standards for hydraulic work.

CALVIN W. RICE, *Secretary*.

PROGRESS ON THE REPORT OF THE BOILER COMMITTEE

Those interested in steam boilers and the steam boiler industry, will welcome news of the rapid progress toward completion of the present revision of the proposed Boiler Code. As a result of the chaotic conditions now existing in this industry, due to the widely varying legislative restrictions and requirements in different localities, the interest taken in this important division of the Society's activities has been almost universal. The important part which this subject played at the Annual Meeting in December, was referred to in last month's Journal (January, page 41); the discussion occupied six separate sessions, aggregating twenty hours in all of continuous meeting, in which the proposed Code and the work of the Committee were discussed in detail.

Since the Annual Meeting, the Boiler Code Committee has been in session almost constantly, studying the criticism and suggestions offered in the Annual Meeting discussion, and has made what is perhaps the most thorough and painstaking revision of the Code that has been undertaken since the inception of the

work. The work of revision has continued without interruption except for Sundays and holidays, for six weeks, including both day sessions and night sessions until midnight. This comprehensive and complete revision indicates how stupendous an undertaking the preparation of this Code has been. The number of important points involved in a matter such as this, and the number of interests directly or indirectly affected have been almost overwhelming to a committee endeavoring to produce a Code that should at once be complete, rational, technically correct and yet free from any ruling that might prove derogatory to the interest of anyone concerned in this industry.

This remarkable undertaking was inaugurated nearly four years ago, the Committee having been appointed on September 15, 1911 "to formulate standard specifications for the construction of steam boilers and other pressure vessels and for the care of same in service." The original instructions by the Council to the Committee were to formulate a model engineers' and firemen's license law, a model boiler inspection law and a standard code of boiler rules. Due consideration was given to the necessity of constructing and installing steam vessels and their appurtenances in as nearly perfect a manner as possible, the importance of preventing carelessness in their operation and the wisdom of having them inspected at intervals by disinterested experts. The importance of the problem was emphasized by the fact that there occur in the United States every year on the average between 1300 and 1400 serious boiler accidents, of which 300 to 400 are violent explosions; these accidents kill between 400 and 500 persons, injure 700 to 800 more, and destroy more than a half a million dollars worth of property.

In the appointment of the Committee which was made during the presidency of Col. E. D. Meier, seven members were selected as follows: A consulting engineer, former member of the Massachusetts Board of Boiler Rules; two professors of engineering; two boiler manufacturers; and an insurance engineer. The Committee began work immediately, the members proposing such an arrangement of rules as their individual experience suggested. It was early decided to use as a basis for the new code, the rules that had for several years been in operation in the States of Massachusetts and Ohio and which were acknowledged to be the best set of rules then in existence. Numerous meetings of the Committee were held during which these rules were deliberated upon and then modified or added to in accordance with the best information obtainable and the Committee's best judgment.

A first preliminary draft of the rules for construction was then prepared, and was sent confidentially to professors of engineering in technical schools, superintendents of inspection departments of insurance

companies, chief inspectors in charge of United States, state and municipal boiler inspection departments, prominent engineers known to be interested in the construction and operation of steam boilers, prominent manufacturers of steam boilers, and editors of prominent engineering journals. A letter was sent with each copy requesting the recipient to read carefully the preliminary report and then to give the Committee the benefit of any criticisms or suggestions he had to offer. All replies were given careful consideration, and at the Spring Meeting of the Society held in St. Paul, on June 16th to 19th, 1914, it was decided to invite all interests affected to appear at public hearings to be held in the Engineering Society's Building in New York, beginning September 15th, 1914. These hearings were the means of bringing together representatives of the steel manufacturers, of the railways, of all classes of boiler manufacturers, also of the American Society for Testing Materials, of the Heating Ventilating Engineers, of the National Association of Stationary Engineers, and of other associations interested.

It is especially worthy of mention that at these hearings, an agreement was reached upon uniform specifications for boiler steel and other material; uniform specifications for boiler tubes; uniform rules for safety valves; uniform rules for fire tube boilers; uniform rules for water tube boilers; and uniform rules for steam and hot water heating boilers.

After the results of the September and October Hearings were thoroughly digested, the Code was entirely revised to incorporate such of the suggestions received as were applicable and another preliminary draft (the third printing) was brought out to facilitate further study of the subject by the Committee and other organizations with which it had been in conference at the Hearings. A very limited number of copies were printed, and distributed to the Committee members and the representative organizations only which had been in conference at the Hearings.

The result of the proofreading of this third printing was a number of modifications in the construction code and the decision to reprint the Code in the fourth printing with the proposed laws, the tables of joint efficiencies and the license application forms omitted. This edition, (the fourth printing) was called a Progress Report and was sent not only to the Committee members and representatives of the conferring organizations but also to every member of the Society, in time for examination and study prior to the Annual Meeting, December 1-4.

It was the result of this Progress Report, which was brought formally before the Annual Meeting for discussion that as reported in The Journal for January, the unusually extended discussion ensued, involving the six sessions from December 1-4, and at these meetings, a large amount of valuable constructive criticism was received on practically all details of

the Code. The importance of this criticism, and the urgent interest of the boiler manufacturers who desire an immediate completion of the work, were the cause of a conference early in December, following the Annual Meeting, between members of the Boiler Code Committee and the boiler manufacturers' associations, at which it was decided that the purpose of the Code could best be served by, first, revising it immediately while the suggestions from the Annual Meeting were fresh in mind and, second, by submitting the details of the revision to representatives from all organizations and interests known to be affected by the introduction of the Code, as proposed. It was felt that the desired result could be more surely obtained by even closer coöperation than had been obtainable in the past, with such other organizations and interests, as they had been shown at the hearings and at the Annual Meeting, to have the detailed knowledge on the many important factors of the work which would be invaluable to the Committee in an advisory capacity.

The result was finally the appointment of an Advisory Committee of 18 members which should sit with the Committee in a final attempt to revise the Code into practical, workable form and thus permit of its presentation at the next meeting of the Society at Buffalo in June in such form that no serious criticism in any magnitude should be heard. This Advisory Committee which was selected to represent all the principal interests involved in the production of the Code includes the following members:

- D. S. JACOBUS, Advisory Engineer, Babcock & Wilcox Company, New York.
- F. H. CLARK, Gen. Supt. of Motive Power, Baltimore & Ohio R. R.
- H. H. VAUGHAN, Assistant to Vice President, Canadian Pacific Ry., Montreal, Canada.
- A. L. HUMPHREY, Vice President and General Manager, Westinghouse Air Brake Co., Wilmerding, Pa.
- KARL FERRARI, Erie City Iron Works, Erie, Pa.
- H. G. STOTT, Supt. of Motive Power, Interborough Rapid Transit Co., New York.
- J. E. MOULTROP, Asst. Supt. Construction Bureau, Edison Elec. Ill. Co. of Boston.
- W. F. MACGREGOR, Supt. of Experimental Dept., J. I. Case Threshing Machine Co., Racine, Wis.
- RICHARD D. REED, H. B. Smith & Co., Westfield, Mass.
- M. F. MOORE, Assistant to President, Kewanee Boiler Co., Kewanee, Ill.
- S. F. JETER, Supervising Inspector, Hartford Steam Boiler Inspection & Insurance Co.
- THOS. E. DURBAN, Gen. Mgr., Erie City Iron Wks., Erie, Pa.
- F. W. DEAN, Cons. Engr., Boston, Mass.
- WM. F. KESSEL, Asst. Mech. Engr., Penna. R. R.
- ARTHUR M. GREENE, JR., Professor of Mechanical Engineering, Rensselaer Polytechnic Inst., Troy, N. Y.
- CHARLES E. GORTON, Gorton & Lidgerwood Co., New York.
- ELBERT C. FISHER, V. P. & Gen. Mgr. Wickes Boiler Co., Saginaw, Mich.
- C. W. OBERT, Assoc. Editor, Am. Soc. M.E., and Secretary to the Boiler Code Committee.

The work of revision was begun on December 15, 1914 and has continued without interruption since that time. It has involved numerous conferences with

organizations and interests in order to settle satisfactorily the few remaining questionable features. It is also worthy of note, that the attendance by the members of the committee has been unusually large in view of the protracted period over which this work has extended (over six weeks continuously).

The work of revision is now rapidly approaching completion, and it will soon be possible for their report to be presented to the Council. If the report meets with the approval of the Council, it will be printed at an early date.

E. D. LEAVITT MADE AN HONORARY MEMBER

Erasmus Darwin Leavitt of Cambridge, Mass., was elected an Honorary Member of the Society at the meeting of the Council on January 12, 1915, in accordance with the vote of the membership by letter ballot.

Mr. Leavitt, who was the second President of the Society and served it during one of the most difficult periods of its early career, was born in Lowell, Mass., October 27, 1836. He was assistant engineer in the United States Navy from 1861 to 1867, and was consulting engineer for the Calumet & Hecla Mining Company from 1874 to 1904. He has also acted as consulting engineer for the cities of Boston and Louisville, Ky., and for Henry R. Worthington and others.

Mr. Leavitt is a member of the American Institute of Mining Engineers, the Boston Society of Civil Engineers, the American Society of Naval Engineers, the British Association for the Advancement of Science, the Franklin Institute, the Institution of Civil Engineers and the Institution of Mechanical Engineers of Great Britain, and is a Fellow of the American Academy of Arts and Sciences. He was awarded the degree of Doctor of Engineering by Stevens Institute of Technology in 1884.

DR. BRASHEAR PARTICIPATES IN THE TRANS-CONTINENTAL TELEPHONE TEST

Dr. John A. Brashear, President of the Society, on special invitation of Dr. Alexander Graham Bell and of John J. Carty, chief engineer of the American Bell Telephone Company, participated in a private test of the trans-continental telephone line from New York to San Francisco on Sunday afternoon, January 24, preparatory to the great gathering held the following day, the events of which are now common knowledge. The lines were connected up with Boston, Jekyll Island and San Francisco, covering a distance of 5000 miles, over which the listeners could plainly hear Dr. Bell in New York talking with Thomas A. Watson in San Francisco. It was Mr. Watson who listened to Mr. Bell in the first message sent over the original telephone.

Dr. Brashear says: "I regard it as a red letter day in my life, although during the past fifty years I have been so intimately associated with the development of science, particularly in the domain of electricity and astronomy and correlated sciences. Wonders will never cease, but this seems to be the climax of great things in electric communication for this century."

THE MELVILLE MEDAL

Admiral George W. Melville, Past-President and Honorary Member of the Society, who died in March 1912, left in his will a bequest of \$1000, the income to be expended upon a gold medal and awarded annually for the best original paper or thesis submitted in competition. It has been decided by the Council that it will be necessary to allow the interest to accumulate for the purchase of a die for the medal before its award is instituted.

APPLICATIONS FOR MEMBERSHIP

Members are requested to scrutinize with the utmost care the following list of candidates who have filed applications for membership in the Society. These are sub-divided according to the grades for which their age would qualify them and not with regard to professional qualifications, i.e., the age of those under the first heading would place them under either Member, Associate or Associate-Member, those in the next class under Associate-Member or Junior, while those in the third class are qualified for Junior grade only. The Membership Committee, and in turn the Council, urge the members to assume their share of the responsibility of receiving these candidates into the Membership by advising the Secretary promptly of any one whose eligibility for membership is in any way questioned. All correspondence in regard to such matters is strictly confidential and is solely for the good of the Society, which it is the duty of every member to promote. These candidates will be balloted upon by the Council unless objection is received before March 10, 1915.

NEW APPLICATIONS

FOR CONSIDERATION AS MEMBER, ASSOCIATE OR ASSOCIATE-MEMBER

COOPER, ELISHA H., Treas., Fafnir Bearing Co., New Britain, Conn.

DINWIDDIE, WILLIAM W., Experimenter, Edison Laboratory, West Orange, N. J.

FARMER, FRANK M., Ch. Engr., Electrical Testing Laboratories, New York.

FLECKENSTEIN, HARRY, with Hindley Gear Co., Philadelphia, Pa.

GULICK, HENRY, Pres., Gulick-Henderson Co., New York.

HAYWARD, HARRISON W., Assoc. Prof. Applied Mechs., Mass. Inst. Technology, Boston, Mass.

HEMMERLY, WILLIAM D., Installation of Scientific Management, The Acme Wire Co., Oven Equipment & Mfg. Co., and Sentinel Mfg. Co., New Haven, Conn.

LANG, WILLIAM H., Secy. and Treas., Phillips, Lang & Co., Inc., Chicago, Ill.

MITCHELL, JOHN R., Representative, W. H. Miner, Chicago, Ill.

MİYAKAWA, KUNIMOTO, Engr. Captain, I. J. N., Admiralty, Tokio, Japan.

MUNN, D. WALTER, Lecturer, School of Mining, Queen's Univ., Kingston, Ont., Canada.

NICHOLS, GEORGE B., Ch. Engr., Dept. of Architecture, Albany, N. Y.

NOLAN, QUINCES R., Supt. of Constr. and Surveys, Park A. Dalls Co., Atlanta, Ga.

NORTH, HERBERT B., Supt., Sentinel Mfg. Co., New Haven, Conn.

NOTTINGHAM, AVON R., Prof. Mech. Engrg., Purdue Univ., Lafayette, Ind.

PEARSON, ROBERT H., Cons. Engr., Globe Indemnity Co., New York.

PIEK, STEFAAN, Genl. Mgr., Niagara, Lockport & Ontario Pwr. Co., Buffalo, N. Y.

PRESSING, RUDOLPH E., Engr., Whiting Foundry Equipment Co., Harvey, Ill.

SKINNER, ORVILLE C., Supt. of Manuf., Standard Steel Wks. Co., Burnham, Pa.

STIMMEL, FRED C., with The Casey-Hedges Co., Chattanooga, Tenn.

THOMPSON, JOHN T., Ordnance Engr., New York.

THURLOW, OSCAR G., Designing Engr., Alabama Pwr. Co., Birmingham, Ala.

WARFIELD, WILLIAM G., Supt., Marion Pwr. Sta., Public Service Elec. Co., Jersey City, N. J.

WARR, WILLIAM, with Robins Conveying Belt Co., New York.

WEIGHT, GEORGE S., Mech. Draftsman and Mech. Designer, Sefton Mfg. Co., Anderson, Ind.

FOR CONSIDERATION AS ASSOCIATE-MEMBER OR JUNIOR

DEPPLEPER, JOHN H., Supt., Goldschmidt-Thermit Co., Jersey City, N. J.

HICKSTEIN, ERNEST O., Mech. Engr., Wichita Natural Gas Co., Bartlesville, Okla.

KOMOW, MAXIMILIAN, Instr. Mech. Drawing and Mech. Design, Murray Hill Vocational School, New York.

MILLER, T. LEE, Asst. to Pres., Toledo Rwy. & Light Co., Toledo, Ohio.

ROLLOW, JAMES G., Combustion Engr., Southern California Edison Co., Long Beach, Cal.

SIMPSON, RALPH, Mech. Tool Designer, Potter & Johnston Mch. Co., Pawtucket, R. I.

WEAVER, WILLIAM G., Lecturer in Mech. Engrg., South African College, Cape Town, South Africa.

FOR CONSIDERATION AS JUNIOR

BOYD, ERNEST M., Draftsman, Mathews Gravity Carrier Co., Ellwood City, Pa.

BROOKE, WILLIAM C., with N. S. Hill, Jr., and S. F. Ferguson, Cons. Engrs., New York.

BROWN, ALBERT M., with Sullivan Mch. Co., Chicago, Ill.

COLDWELL, JOHN S., with Alberger Pump & Condenser Co., Newburgh, N. Y.

FIELD-FRANK, CROSBY, Cons. Engr., New York.

HAZZARD, WILLIAM S., with Southern Adjustment Bureau, Atlanta, Ga.

KARR, ALFRED D., with Tiffany & Co., Silver Wks., Newark, N. J.

KESSLER, RAINES, with The Terry Steam Turbine Co., Hartford, Conn.

LOCKWOOD, WILLIAM G., Asst. Ch. Engr., Pierce Phosphate Co., of the A. A. C. Co., Pierce, Fla.

LOW, FREDERICK H., with the Ford Motor Co., Highland Park, Mich.

MONTGOMERY, GRAHAM L., Inspector of Constr., Brooklyn Edison Co., Brooklyn, N. Y.

NEVINS, WALTER I., Asst. to Steam Engr., Inland Steel Co., Indiana Harbor, Ind.

POPE, SAMUEL A., with William A. Pope, Chicago, Ill.

POUND, JOSEPH H., Instr. in Mech. Engrg., Rice Institute, Houston, Tex.

PREST, HAROLD M., with H. R. Worthington Hydraulic Wks., Harrison, N. J.

RUSH, EARL S., Draftsman, Iola Portland Cement Co., Iola, Kan.

WEGENER, FRANCIS A., Asst. Master Mech., Welsbach Co., Gloucester, N. J.

WOLFENER, IRA W., Asst. Treas., Natl. Cooperage & Woodenware Co., Peoria, Ill.

APPLICATIONS FOR CHANGE OF GRADING

PROMOTION FROM ASSOCIATE

HILL, HAROLD H., Mech. Engr. and Dist. Mgr., Erie City Iron Wks., Cleveland, Ohio.

PROMOTION FROM JUNIOR

HEBERD, LOREN L., Mech. Engr., Vaughn, Meyer & Sweet, Cons. Engrs., Milwaukee, Wis.

MUDD, JOHN P., Engrs. Dept., The Midvale Steel Co., Philadelphia, Pa.

RUTE, ERNEST L., Genl. Mgr., Bayonne Bolt & Nut Co., Bayonne, N. J.

PUBLIC SERVICE MEETING

THE feature of the Annual Meeting held in December was the Public Service meeting which required the entire day on Thursday, December 3, and some time on Friday morning. These sessions were arranged by the Public Relations Committee, who desired to draw to the attention of engineers the opportunities for the application of their special training and knowledge to the many important engineering problems that confront the large municipality. The papers and discussion showed the broadening field of work for the engineer and the need for a public-spirited service in civic affairs. There were nine papers presented, which are here published in abstracted form, together with a brief account of the discussion.

At the opening session of the Public Service meeting held on December 3 during the Annual Meeting, brief remarks were made, previous to the presentation of the professional papers, by the Hon. John Purroy Mitchel, Mayor of the City of New York, by Andrew Carnegie, Honorary Member of the Society, and Dr. John A. Brashear, President-elect.

President Hartness who presided said, in introducing the Mayor, that in other days the engineer was needed in the administration of cities; but the modern city has grown to be a piece of mechanism—the more modern the city, the more complicated the mechanism. The highest type of modern city is the great city of New York and the Society was honored in having its Mayor as a guest.

Mayor Mitchel said in the course of his remarks that while at the present time nearly every one of the great constructive activities of the city was in the hands of engineers, yet there is still great need of assistance in working out the problems of administration, public and civil service, accounting, and all the multiplex activities of a city government represented by its administration departments.

Mr. Carnegie eulogized the work of American engineers and commended the Mayor in his aims in solving the difficult problems presented in city government, concluding with a few facetious remarks at the expense of Dr. Brashear, his intimate friend. Dr. Brashear replied in kind, speaking also of the valuable assistance Mr. Carnegie had rendered in an important research which he had just completed and of the pride taken by the people of Pittsburgh in the great educational and scientific institutions made possible by Mr. Carnegie.

THE FUTURE OF THE POLICE ARM FROM AN ENGINEERING STANDPOINT

BY HENRY BRÜERE, NEW YORK

Non-Member

The author states as his reason for a discussion of the problems of police administration at a meeting

¹City Chamberlain, Municipal Bldg.

Abstract of paper and discussion presented at the Annual Meeting, December 1914. Complete paper may be obtained without discussion, price 5 cents to members; 10 cents to non-members.

of mechanical engineers that the most neglected field of public service in America is the police department. There is no part of municipal administration, not itself in the engineering category, that more urgently needs the aid of engineering method than does the "police arm." He makes this assertion on two assumptions, with which, he says, there may not be general agreement. The first assumption is expressed in a definition of the substance of the "engineering method." The second assumption is expressed in a definition of the functions of the police arm. These definitions are as follows:

a The engineering method consists of applying scientifically determined knowledge to the execution of a particular problem, and the use of ordered and analyzed facts as a basis for formulating conclusions in respect of that problem. As a result of the repeated application of the engineering method to like or similar problems a technique is established for achieving a particular object repeatedly, with least waste of energy and resource

b The function of the police arm of government is to ascertain all the facts regarding the phenomena of crime and disorder, and by the use of those facts as a basis for action, direct and collateral, to minimize and extirpate crime and disorder

In respect to the functions of the police arm the author says that generally, until now, the functions of the police have been assumed to be something as follows:

a General enforcement of certain laws and ordinances

b Enforcement of certain other laws and ordinances selectively, according to the feasibility of their enforcement and the state of public opinion regarding them

c Enforcement of certain other laws and ordinances on complaint of persons injured by their infraction, with particular respect to the perpetrators of the injury

d Repression or prevention of crime and disorder, by the process of tacit intimidation; in other words, the brass buttons and swinging night stick

e Physical and militaristic suppression of express disorder, such as riots and street brawls

- f Investigation of crime committed for the purpose of tracing, identifying and apprehending the criminal
- g Performance of inspections, regulation of traffic, rendering aid to citizens, and miscellaneous other incidental functions that are committed to the police as matters of convenience, and are not generic to the police problem

The one common ideal of police service that has been developed in American cities is that the police must be physically well-conditioned and personally honest. This is about as far as any American city has gone, with the possible exception of Toledo, under the rule of Brand Whitlock, and New York City today under the administration of Mr. Mitchel and Mr. Woods.

In the minds of the conventional police, criminals divide themselves into four groups:

- a Aliens, enemies of society violating the rights, safety and peace of a community, "to be put away," thus gotten rid of
- b Native incorrigibles, endowed with natural perversity, namely, the familiar thug, the gangster, the crook
- c Fortuitous criminals who become subject to police action because of moral lapse or temporary aberration

or as belonging to

- d A miscellaneous group including special and individual cases too numerous to catalogue, but comprehended generally in 174 items of the standard crime classification, as used, for example by the New York police

There has been no recognition of crimes as the consequence of remediable social conditions or the effect of individual abnormalities, either physical or mental, resulting from removable causes.

There should, however, be a statistical basis for police work, as there is a statistical basis for engineering work. There is nowhere in the world a collection of social data so potentially useful to the development of a community as lie in every great municipal police department, in the records of arrests, in the records of crime disposition, in the investigation of crimes, in the note-books of policemen and in the memoranda and reports of detectives.

In the report of the New York police department for 1913, the only reference to these records is found in a single sentence under the heading Bureau of Records:

During the year 1913 there were received and filed in the Bureau of Records a total of 35,013 documents.

New York City employs 11,000 policemen who made 119,736 arrests in 1913. It has a detective bureau of 150 detectives who investigate 55,000 cases of crime a year, but it has not a single employe engaged on an analysis of the facts brought into the archives of the department in the form of reports on investiga-

tions and records of arrests. Commissioner Woods is the first police commissioner in America, so far as the author knew, who has thought it worth while to put in his budget a request for statisticians. Next year he will have a statistician under the supervision of a deputy trained in statistical analysis, who will study current police conditions and police work. Not only is he taking this step, but he is utilizing every member of the force as an agent for gathering social facts respecting such matters as unemployment, destitution, improper guardianship, upon which intelligent police work must be predicated.

While it is generally known that economic distress and unemployment lead to an increase of small crimes against property and the breakdown of natural self-control, no American police department has ever analyzed its records to correlate degrees of unemployment with perpetration of crime, and thus furnish the basis for police activity with regard to unemployment. New York City, however, has had this matter forced upon its attention. Conditions of unemployment last year furnished the opportunity for anarchistic agitation, demonstrations of violence, invasions of churches and other disorderly practises, on the avowed theory that only in this way could the public be brought to realize the crucial importance of unemployment conditions.

These violent manifestations of disorder, which had their relation to conditions of unemployment occurring in 1914, make it seem a natural function of the police to ascertain the facts regarding conditions of unemployment in 1915. The police department is the logical agency to call the attention of the community and other branches of the government to the need for taking some constructive steps to mitigate abnormal unemployment.

In New York, one of the principal problems confronting the police is control of traffic. It was never conceived by the builders of modern cities that thoroughfares, intended for residential purposes and often crowded with children, would be utilized by high powered motor trucks and automobiles, and that many streets designed for local traffic would become the thoroughfares of a vast population. As a result of this condition there are killed each year in the streets 445 persons.

It is peculiarly the function of the police department to work out means of preventing this appalling condition, because the police department is charged with responsibility for regulating traffic. Up to January 1st of this year, New York City's police did not record information necessary for an intelligent analysis of the conditions surrounding the death of persons in the streets, although they are required to report the facts regarding each occurrence as a part of the coroner's investigation.

By focusing the attention of police captains and patrolmen on the incongruity of using congested traffic

streets for play spaces for children, the present police commissioner obtained from patrolmen and their officers suggestions concerning the use of vacant lots for play purposes and for closing to traffic during certain hours of the day streets used by children for play. The mere fact that the police themselves formulate such suggestions and assist in putting them into effect, brings about a psychological change in the attitude of the policeman to his community relationships which is full of the greatest possibilities for the development of police service. It is merely another illustration of applying the scientific or engineering method to a particular problem, instead of continuing along from year to year, from generation to generation with fatalistic resignation to whatever may happen.

The author anticipates possible criticism of his suggestions that they overlook the necessity for dealing with criminals as criminals and maintaining law and order by vigorous police action. It is no part of this suggestion that law enforcement be relaxed. A sentimental attitude towards breakers of the law and violators of the public peace and social rights of the community is not advocated. On the contrary, a very drastic action is favored regarding them where such action does not defeat its own purpose. It is recognized that the existing product of social environment, of disease, of mental degeneracy, of moral perversity, cannot be dealt with through eliminating conditions which breed them, but have to be dealt with through our penal machinery, and will probably sooner or later, for the protection of society, become the subject of police action.

A very considerable part of present criminality can be eliminated by intelligent preventive action. This preventive action should be initiated, if not actually taken by the police. To initiate it intelligently, the police must act not on general information or impressions, but on carefully gathered data. These data will not in every instance point to clear conclusions or be capable of definite analysis. The work of correlating crime to social conditions is practically untried. If law and order lie at the basis of industry, if social adjustments are essential to economic welfare and civic development, then no section of the community can ignore the police problem. It is particularly important that engineers who are the expert advisers of our industrial and economic life should make their special experience available to police administrators in formulating a method for arriving at the facts underlying the police problem.

The latter part of the paper deals with police organization. Involved in this are questions of training of officers; selection of officers; ratings for efficiency and selection for promotion; enforcement of discipline; methods of compensation; welfare activities, including educational work, medical supervision and provision for insurance and pensions. These various questions are discussed briefly. The author says further:

The outstanding fact regarding conventional police organization is that it is military, and the outstanding fact regarding military organization is that it is not intended to accommodate itself to shifting social development, to relate itself intimately to community life, to be sympathetic and understanding, or to be flexible. Military organization deals with individuals as subservient members of a group and not as self-governing factors coöperating in the execution of an undertaking. In police departments it has aimed at the one consideration everywhere recognized as fundamental in police work, namely, personal integrity. The military assumption of moral and mental dependence of subordinates on superior officers, has, however, been one of the great weakening forces of police work. In the case of policemen, personal integrity results from exercise of self-restraint in inhibiting an impulse to accept a bribe, to connive at a violation of the law, or to practice extortion. The faculties needed to resist temptations of this character must be developed through a process of self-reliance, through a formulated, even though rudimentary, philosophy of personal conduct. The soldier ceases to be responsible for his moral conduct once he places himself under the command of a superior officer. This condition, while of course less marked in police service than in a purely military organization, still prevails to a certain degree, and has been a conspicuous embarrassment to the development of individual police initiative in larger American police departments. Mr. Woods, New York's present police commissioner, has no military training or sympathies, and is dealing with the officers and men of his department on the assumption that they are self-controlling and self-initiating centers of police thought and police work. This method is a promising contrast to the policy of the martinet, or a policy of easy tolerance, that customarily prevails in police work, and stands out against the old conditions as strikingly as the modern, enlightened employer's policy in industrial management does against the old time shop boss method of dealing with workmen.

The future development of the police arm, if police work is to be constructive and to fulfill its possibilities, must be along the lines of the engineering method. The police department through its multitude of agents is the best equipped of all social agencies for apprehending sympathetically and certainly those adverse social conditions in the community which can be remedied only through community attention. The police department should be the eyes, ears and feeling fingers of the city government. If it finds through its investigation and observation that recreation facilities are inadequate, that this bears upon crime conditions and the welfare of the city's youth, those facts should be driven home to the educational and recreative departments, and in the same way with other conditions.

The police department of a great city should be the nerve center of the city's government, capable of acting with vigor when a situation demands vigorous treatment, strong to protect the safety of the public against disorder and the unruly, informed on conditions which manufacture crime and criminals, in order that these conditions may be remedied where remedies are possible; aggressive instead of defensive, courageous instead of fatalistic, organized for achievement instead of for mere opportunism, militant but not military, except in the sense of obedience to necessary rules and responsive to discipline; free to deal honestly with conditions in the light of those conditions instead of in the light of statutes written by dead hands; cooperating intelligently with charities, corrections, health, hospitals, and educational departments.

To bring these things about the police problem must be broken up into its proper functional divisions. Crime when perpetrated by professional criminals must be dealt with differently from crime committed by those who stray temporarily from the paths of rectitude. There should be organized a national service for the detection of criminals and crime prevention along the lines of similar service now engaged upon forestalling and detecting counterfeiters. The voice of the police department must be heard in the courts when punishment is meted out to criminals, not because it is the police department, but because it is informed and expert on questions of penology.

Above everything else back of police work there must be developed a scientific spirit, the true engineering spirit; in place of cunning and endgels there must be substituted a policy based upon a knowledge of needs, standards of service feasible of attainment and organization devices to accomplish them, methods of administration and the plant to facilitate their accomplishment, and the genius to capitalize the initiative and individuality of every man on the force.

DISCUSSION

R. P. BOLTON congratulated the author on the discovery that there is a purpose in engineering methods and that there is also the possibility of advantage to one department of city government in the utilization of engineering methods.

The rights of a citizen extend to the exercise of police powers on the part of any individual, and the police are no more than paid delegates of citizens performing this duty for them. The question as to whether these men should be regarded from a militaristic or departmental view has more than one side, the advantage of military organization consisting in the addition of *esprit de corps* to the moral character of the police officer, while the provision of weapons is of dubious value, and certainly tends toward suggestive imitation on the part of other persons.

The author's suggestion that the police should be charged with the study and dissection of the causes of crime would lead to doubtful results, since the work is in itself a function

of scientific investigation, and the local police would be confined to the study of local causes, which might be misleading. The proposal would only result in additional jobs in scientific bureaus added to the police department, and publicity given to such statistics and information might have an unfortunate result in suggestive inducements to crime.

Some at least of the accidental deaths in the public streets are due to the neglect on the part of our Department of Public Works to provide proper isles of safety, in view of the crowded conditions of traffic.

The author spoke of the prevention of crime by the provision of ample street lighting, but has himself taken a personal part in the recent reduction of city lighting, in the interests of a parsimonious economy.

He believed the difficulties experienced in upbuilding the character and in extending the usefulness of the police force are attributable to causes entirely different from those advanced by the author. He had found a feeling prevailing among the men that they are denied a recognition of loyal service on the part of their superiors and of the public, and are subjected continuously to unfair treatment by politicians and by the newspapers, and also that the magistrates almost unanimously seemed to regard a police officer as either a liar or a scoundrel.

He agreed with the author as to police pensions, but pointed out that this condition is applicable to all classes of city employes. The essential error in this system lies in the provision of pensions paid to idle men still capable of work. The process should be entirely changed, so that increasing age should be met by a proportionate reduction of labor and not by payment for idleness, and the value should be recognized of the continued service of experienced and faithful employes long after their full physical capacities could be exercised.

The application of engineering methods to the problems of the police would include the recognition, prior to the question of efficiency, of the value of loyalty, of merit and long service, and also the establishment of a system of fair treatment of the members of the force.

CLEMENT J. DRISCOLL¹ in a written discussion said that the cause for police inefficiency in New York can be found in the fact that in 13 years the department has had 10 police commissioners. Not one of these doubted the efficiency of the engineering methods and not one did not fully realize before he retired, or was forced to retire, from the department that the police problem was such that only careful, patient application of scientific methods would solve it. All of them would say to the engineers gathered here that all the methods known to science would be of little value while the control of the department was in the hands of the political powers of a community. The Panama Canal, one of the supreme engineering feats, was made possible only because the engineer in charge remained on the job long enough to work out the engineering problem. But even Mr. Goethals would not have mastered the police problem of New York by the application of the engineering method if he had been subjected to the conditions under which all the administrative heads have had to work. No matter how determined a police commissioner may be to keep his department free from politics, it will be subjected

¹ Bureau of Municipal Research, New York City.

to political influence so long as he himself is subject to arbitrary removal and the mayor of a city is held responsible for a police department and its management.

In summarizing, he urged as the first step toward increasing the efficiency of the police, the adoption of statutes providing for a more permanent tenure of office for the administrative head; second, the complete separation of the police department from the mayor's office, placing the full responsibility for the administration and conduct with the police commissioner or administrative head, regardless of his title; third, the application of the engineering method; and, fourth, the complete abolition of the system now in vogue throughout the country of adopting policies of law enforcement which will result in the enforcement of the statutes as written.

ALEX. C. HUMPHREYS said that his chief reason for speaking was to pay a tribute to Mr. Brûère, and to say that he was sorry that the discussion could not have been more appreciative of Mr. Brûère's courtesy. He said there was no fundamental inconsistency between Mr. Brûère's paper and Mr. Driscoll's discussion, though some other inconsistencies are apparent in connection with the discussion. He suggested to the New York citizens present that they had better not take upon themselves the task of being their own policemen; they might get into trouble. They can, however, advise and they can educate the public as Mr. Brûère had advised, and here he differed from the last speaker. He saw no reason why Mr. Brûère's suggestion with regard to a bureau cannot be carried out. The direction would have to be in the hands of a man qualified for scientific investigation. Under such direction of such a man the facts could be gleaned from the rank and file of the force. This would involve no inconsistency but might be a tremendous agency for the education of the public; and if the public could be sufficiently educated, the politics of the situation would be taken care of. The speaker said that he agreed absolutely that the present troubles in connection with police control are largely due to the interference of politicians.

The Author disagreed with Mr. Driscoll in saying that the greatest difficulty in this matter is politics. There is no politics in the police department for political reasons. The reason is that the police department does not know what the gang problem is. The thing that is most needed is not the elimination of politics, but more of the kind of politics that men such as the engineers present would uphold.

In answer to Mr. Bolton, he did not recall having suggested that a new bureau be established. He suggested that there be given to the police department the facts regarding outside conditions, not gathered by impressions, but based upon the actual experience of the department. There is no problem which Mr. Bolton has ever been called on to face that he does not or should not reach in the same way. And in engineering questions, the question of lighting public streets, in which he has an interest, cannot be solved by a general assumption that a lot of light is going to reduce crime. On this theory one can get ten times too many lights. Lighting under such circumstances may not reduce crime at all, but simply add to the payments made by the city to the lighting company. In settling the questions of lights and of gangs, the police department has to approach the problem

just as any engineering question must be approached. If gangs exist because they have the protection of politicians, that cause ought to be ascertained.

His plea was that we proceed with regard to this whole question on the basis of facts, not on that of passion or sentiment, or of politics, or of impulse or judgment. He asked engineers not to find a way of putting on the shoulders of others the responsibility for existing conditions, but to take it on their own shoulders. To have, as some one suggested, a police commissioner continuously on the job would not mean success in police administration. He could not understand his problem merely by continuity of service, but would have to employ the engineering method advocated by the author.

He hoped that as a result of this conference some thought would be given in each community represented to getting a fact basis for police administration, so that in dealing with this most easily complicated division of city government we shall not have to act merely upon passion, impulse or newspaper headlines.

SOME FACTORS IN MUNICIPAL ENGINEERING

BY MORRIS LLEWELLYN COOKE.

PHILADELPHIA, PA.

Member of the Society

The author calls attention to the wide opportunity for the activity of engineers in municipal work and to the fact that at the present time a large part of this field is either not covered at all or covered by non-technical men. The author emphasizes, however, the necessity for the cultivation on the part of the profession of a broader and more collective interest in public affairs. In this he follows up the theme advanced in a paper read some years ago before our Society under the title "The Engineer and the Public." There is a note of warning that with the growing consolidation of manufacturing and other enterprises, especially in the utility field, there is danger that the cities of the country will be left without proper engineering advice in certain of their engineering questions. The author points out that the matter of viewpoint and a genuine public interest are as essential in the engineer who is to advise a city as ability and experience.

An important part of the paper is the author's reference to the function of advertising, both as affecting the professional activities of the engineer and in the movement to educate the public to the necessity for having public work done on an engineering basis. He holds that certain kinds of municipal engineering, street cleaning for instance, are based on a growing appreciation on the part of the public of the factors of the problem and that this

Abstract of paper and discussion presented at the Annual Meeting, December 1914. Complete paper may be obtained without discussion, price 5 cents to members; 10 cents to non-members.

can only be developed through systematic and aggressive advertising methods.

The effectiveness of the engineer in public employ is very largely dependent upon the support given to him by his profession in the education of the public to proper policies of administration. The engineer holding a public position is not "in politics" and to be a success must have the collective support and advice of his profession. There are too many matters that should be determined by technical and scientific considerations now decided by vote. Attention is called for instance to the archaic systems of appropriation and control of the budget now in general use in our municipalities with suggestions for remedies.

Civil service as it applies to filling the higher technical positions is referred to and a note of warning sounded as to the growing complexity of all governmental problems. Lines along which municipal agencies may be simplified are indicated, and a suggestion is made for a municipal reference library as a branch of the Engineering Societies' library.

Quotations follow from different sections of the paper:

The test by which the role of the engineer is to be determined will be the development in our profession of a genuine spirit of public service. The community is apparently ready to accord the engineer a leading, perhaps a controlling part, if the engineer will consider that in every decision and act there shall be the clearest possible recognition of the public interest. We should remember that democracy can use the engineer without giving him either a leading or a controlling hand in affairs. This use of engineers has been conclusively demonstrated by public utilities companies, especially during the last thirty years. In most of our larger cities during this period there have been operating one or more so-called "big business" men who have built large fortunes and a certain kind of fame in the development of enterprises in which engineering was an important factor and in which it should have been the paramount and controlling factor. In these enterprises engineers have necessarily been used, but not in a leading or controlling capacity.

It would probably require considerable research to get the names of the engineers used by Charles Yerkes in Chicago; by Martin Mahoney in Philadelphia; by Anthony N. Brady in New York; and by Patrick Calhoun in San Francisco. As a profession we may as well face this problem and decide whether in the further upbuilding of our cities, we are so to serve democracy as to be warranted in demanding and to be entitled to receive a position comparable to the real importance of our work.

That profession which considers only its own and its clients' interests without a proper regard for those of the general public will be accorded the same position which history has always given those who are led by no higher star than self interest, however enlightened that self interest may be. I firmly believe that the engineering profession is rising to meet its broader responsibilities with perhaps an even more quickened pace than that which during recent years has wrought such sweeping changes in the medical profession and that of architecture. There are certain kinds

of engineering in which financial and almost all other kinds of preferment depend on an attitude of mind which, while not necessarily anti-social does not provide sufficient opportunity for entertaining a virile public point of view.

As a representative of public, rather than private interest, it is my duty in choosing the advisers of the city, which I have the honor of serving, to satisfy myself not only as to the ability of those we employ, but also as to their disinterestedness—yes, their public point of view.

No matter how able a man may be, how broad his experience nor how high his standing, his service to those who employ him must at all times be consistent with the public interest if, from my point of view, he is to be available for public employment.

Judged by this standard, there are in certain fields of engineering almost no engineers who are at present available for the service of the public and who at the same time have had sufficient experience for large undertakings. In the past few years we have had unusual opportunities for seeing at close range the professional attitude of those equipped with the technical knowledge required in advisers to cities on utility matters. It has been practically impossible to secure the services of those with reputations already made in the electrical field. Some of our experiences could be considered on the whole rather amusing were it not for the fact that we are left under the obvious conclusion that for the average city official to get good advice on these matters, is well nigh impossible. What is more objectionable is that this condition is one quite generally recognized as true by city officials.

I must be careful to emphasize the fact that no criticism of any individual is embraced in these remarks and that I am simply pointing out a danger almost necessarily confronting the engineering of an industry dominated by financiers having no knowledge and little appreciation of such professional standards as engineers are supposed to have.

The same tendency is to be noted in other branches of our profession. An eminent authority on concrete, who is in intimate touch with the men who are practising in this line, was recently asked for the name of an engineer who was not in anyway affiliated with the large manufacturers of this material and after considerable study was able to think of only one man. There is nothing necessarily improper in this situation,—it may simply mean that all the competent men in this line receive retainers from manufacturers. Some months ago I wanted to retain an engineer fully posted on the details of a certain sub-division of railroad operation. It was extremely difficult to find a man without recognized affiliations which would preclude his retention. Again I am informed that there are no asphalt experts who do not receive retainers from the manufacturers. It is a condition which should be provocative of thought by engineers.

Public employers up to the present have been almost a negligible factor in furnishing opportunity for employment or for the making of a reputation. It is perfectly natural, and it is in accord with former ideals that engineers should feel their first duty to be to these private employers. But in this time of broader and deeper social consciousness, it seems to me that this standard must change.

The point I wish to make is that engineering has now reached the stage of development where it has become a profession in the highest sense of the word. The engineer

being a scientist, his responsibility should be for the development of facts, regardless of whose advantage they may serve. I have in mind that the service of an engineer should be as the service of a judge, as opposed to the service of a lawyer who confessedly seeks out and represents the interests of his client, and often "makes the worse appear the better cause." This is justified by the fact that lawyers are not scientists, and by the assumption that there shall always be opposing counsel.

If this municipal field is to be one in which engineers of ability, sincerity of purpose and high ideals are to find a permanent and satisfactory outlet for their energies, our profession acting as a profession will be one of the main agencies bringing about certain fundamental changes in the attitude of the public. In the minds of too many engineers, participating collectively in matters pertaining to municipal engineering means "getting into politics." Architectural work being a part of the business of The Department of Public Works in Philadelphia, we have had the coöperation of the American Institute of Architects and of its Philadelphia chapter from the beginning. . . . We have had the constant, indefatigable and valuable support of the secretary of The American Society of Mechanical Engineers in our efforts to maintain the highest professional standards in the work of the department. But engineering bodies as such have given us no assistance and so far as I know have taken no part in the discussion of federal, state and municipal engineering, except in the matter of conservation which for some reason is considered as innocuous as a prayer meeting.

Many municipal engineers in this country are beginning to adopt the European system of employing non-residents for certain highly specialized positions. Whenever this is practised it excites criticism and abuse. As yet no technical organization, so far as I know, has recognized the opening thus made for technical merit and given moral support to the movement. Again I have tried to get support from organized engineers in the obviously necessary procedure of employing experts outside our regular staff, but without results.

The public must be taught that public service is not different from private service in that forward steps come frequently, even usually, as the result of a large amount of preliminary investigation. Again, the public, of which please remember we are a part, must be educated to place more responsibility on individuals, thus making it possible to do away with the great inefficiencies which inevitably accompany board and committee management. As long as we have boards and committees they will vote,--and they will insist on voting,--on matters that are not questions of personal opinion but questions of facts which ought to be determined by the facts. It is one of our duties as technical men to carry on a propaganda which will show to the public the difference between those problems of policy and public interest, that are properly settled by public opinion and those scientific problems which are improperly settled unless they are settled according to the facts. Mr. Frederick W. Taylor, Past-President of the Society, in recent lectures has very forcibly and lucidly suggested this fundamental difference. For instance, my opinion may be as good as that of any other citizen's as to how fast an automobile should be allowed to operate in different sections of a large city. The opinion of any member of this Society

is as good as that of any other citizen as to the penalty which should be inflicted for false registration. On the other hand, the designs for a bridge; or the specifications for a sewer; or the plans for the laying out of a public park; or the organization of the police department; or the fighting of fires; or the elimination of mosquitoes are necessarily the work of experts. Such work will always be indifferently done if done by voting; whether the voting is by the people at large or by a committee or board acting for the people. Notwithstanding all the boards and commissions that are created in the generally approved laws of today, there should be no uncertainty as to what questions they may vote upon. It is therefore one of the duties of the educated to carry this message to the people and in doing so I do not think there will be any more powerful method than to give the great mass of the people a larger and larger knowledge of expert work.

I am not one of those who feel that all our short-comings are "the fault of the people." I would rather assume my share of the responsibility for conditions as they are and then join with my professional associates and the community at large in bettering them. If we engineers are to have any prominent part in this there are fundamental changes which we shall have to make in our own equipment for the work. In the first place, we have to get rid of the now old-fashioned idea that advertising is a crime. I admit that as a part of my work as a public official I put in a great deal of thought on what may be quite properly called advertising. By that I mean that I pay less attention in my reports to dignity of form and diction than to making them sufficiently interesting to be read. It is only as we engineers who are public officials learn to make the public, sometimes against its will, understand our work, that we are to get that degree of popular support for it which will make it possible for it to be done in an efficient manner.

In my opinion it is going to become more and more a necessity, not only in public but in private work, for engineers to be able to popularize what they are doing. It is true today that a man who wants to do really good and efficient work can do so only after an aroused public opinion. You cannot drive people in a democracy. So I admit that in offering employment to an engineer, other things being equal, I want what might be called a good advertiser. You can secure appropriations for work more easily when it is well advertised. The Panama Canal is a good example of this principle. Again, advertising is the best possible check against ill advised expenditures. In building our Hyberry and Bensalem Service Test Roadway we erected sign-boards on each of the 26 sections giving to the layman the exact method of its construction in non-technical language. If the public knows how a street is supposed to be constructed or cleaned, you do not require as many paid inspectors on the job.

The development of some varieties of municipal engineering is absolutely dependent upon the development of public opinion and must proceed with it. The matter of street cleaning is largely a question of an improved public taste in the matter of street paving. Unless streets are well paved they cannot be well cleaned except at a prohibitive cost. To jump from one degree of cleanliness in this respect, to another, without a supporting public opinion, may be enough to wreck an administration and to set the

tide of civic improvement running in the opposite direction.

The newspaper is the great educator in these matters today. But we are already using in Philadelphia moving pictures, parades and exhibitions. The possibilities of these and other means of publicity are not yet fully understood.

Take, for instance, the movement which has led to the formation of large numbers of business men's associations and improvement associations. This affords one of the very best examples of the present vitality of American public life. Our leading men should accept them as something that has come to stay and coöperate with them in such a way as to direct their activities into profitable channels. It seems to me they afford the most promising agency through which in the first place, the thought of the public on civic questions can be crystallized and secondly through which that thought can be given expression in definite public procedure. I have found these associations ready and anxious to hear from men who had definite knowledge on matters of public interest. It should be the attitude of any engineer who wants to play his part in the community, to affiliate with one of these organizations and to help to make it an influence. You can rest assured that the man who is in public life for his own personal advancement is bending every energy to defile and degrade these institutions and to divert them from the high mission which they have it in their power to carry out, so they need our help.

In such a discussion as this, one cannot ignore the civil service. It is always a pleasure to say that personally I could not hold public office if it were not for the safeguards and reliefs that our Civil Service Act affords. At the same time without repeating what I have said in other public papers on the subject, I want to call attention to one fundamental misconception under which the entire civil service question in this country apparently rests. Civil service appears to be founded on the theory that the best man for the position will apply for it. I think it is the experience of every employer of men—and this is especially true in filling the higher positions—that the best man will not apply. On the contrary you will usually have to go out on the scriptural highways and hedges to find the best man and then having found him, fall on your knees and beg him to accept the positions offering such opportunities for public service and professional independence as are most likely to secure him.

This is the way to get good public servants. It is almost impossible to find men who have many of the qualifications for our work combined with a willingness to enter the public employ. Even if public employment should come to be considered more desirable than it is at the present moment, I think that this difficulty in finding the best man would still be encountered. Therefore, if we are to have the highest class of men in important engineering positions we must develop some merit system by which the appointing officer is given a greater opportunity than he now has of finding the man for the job. In this work it is impossible for our engineering societies to take an important part.

I believe, for instance, that if the secretaries of the four national engineering societies could be authorized by their several councils to associate themselves as a civil service board to act in an advisory capacity to federal, state and municipal civil service commissions, it would be a decided step in the right direction. Suppose the president of the

Borough of Manhattan should want to secure a competent engineer to put in charge of the highway department. Through the New York City Civil Service Commission he would state the problem to this suggested advisory board which in turn would appoint say three engineers to act as his counselors in finding the man. The appointing officer would keep these counselors in touch with the search and when he was ready to make a choice, secure their approval before entering into a contract. In this way the merit system would act as a check against favoritism but would allow the appointing officer the widest possible opportunity to search for the best man available.

This procedure is a radical departure from the present idea of civil service, which is based on the assumption that it is impossible to allow the appointing officer to have anything to do with the selection of his men. Even under the most advanced forms of civil service the appointing officer is confined to a full statement of the qualifications he is trying to secure. One never exactly fills a position with just the kind of man in mind when the search started. It is a question of compromise and the appointing officer is the one who is in the best position to know where concessions can be made and which among the several requirements are the most indispensable. There would be no objection to a check on this action of the appointing officer through some kind of a written test. But to choose men for positions paying \$5,000 to \$25,000 a year on the results of a written examination is absolute folly. So far as I know engineers have never taken a hand in the discussion of methods under which engineers shall be chosen for positions in the public service and it seems to me high time they should do so.

Among other subjects in the paper not covered in the foregoing extracts is that of records of data upon investigations and work accomplished by municipalities. Not only are such records very meagre, but they are practically unavailable except to those who make them. As a practical suggestion, the author believes that a distinct contribution which the Engineering Societies could make to the solution of the question would be to establish in the library a section devoted to a Municipal Reference Library. At the present time there is no possible way for a city official to be sure that manuscript reports on engineering matters will be available twelve months after they are made. The author had, for instance, a digest on American street cleaning methods prepared by Day & Zimmerman, Consulting Engineers. It is an exceptionally valuable document. He knew where it was today but there was no possible machinery provided in Philadelphia or in any other city whereby officials could be sure that they could find such a report a few months after its preparation. This manuscript would be of very great value to any city official charged with the problem of extensive street cleaning. He would be glad to deposit this report in any library properly organized to receive it.

The same is true of literally dozens of reports on gas, lighting, electricity, garbage disposal, city plan-

ning, police discipline and others prepared under the present administration in Philadelphia. He knew that, if this suggestion was adopted and such a library was started, city officials all over the country would be glad to have extra copies made of every report which should properly belong to such a library.

DISCUSSION

ALEX. C. HUMPHREYS said that while he was in sympathy with much of that presented by Mr. Cooke, he differed from him strongly as to details and in so doing he was guided by a wide experience with engineers and municipal governments.

He believed there was not the slightest difficulty in getting the right kind of engineers for the work referred to, if they were properly approached and fairly treated. If, on the other hand, one approached these men with the idea that because they have been in a certain line of work, they must necessarily be biased in their opinions, one should not expect to get the best results.

The speaker was unable to understand why it should be recommended that a library on municipal engineering should be set apart from the rest of the library. If this should be done for municipal engineering, why not for all other branches of engineering. Then, where should the lines of division be drawn. He was reminded of the advice he had given some time ago regarding a certain book on the finances of public utilities. This book was misleading in the hands of the uninformed by reason of its plausibility. The advice given to those directly concerned was to purchase the book and so be prepared to controvert its false teachings, particularly as this could be done through its own inconsistencies and contradictions.

As to the absence of standards, the speaker thought that the trouble in large measure was that sufficient attention is not given to the fact that working standards can be established only by taking all factors into account; the scientific, upon which there is so much stress laid, and also the practical factors, including the necessary limitations of application,—the commercial, the financial, and the human.

If standards are being developed for the guidance of others, such work must be done cautiously and with a keen appreciation of the responsibilities assumed. Enthusiasm alone is not only not sufficient but may be most dangerous. Those who undertake this work must first of all be competent to do it, and then must secure the faith of those in control with regard to their integrity. The speaker was emphatic in saying that he resented the pervading tone of the paper, which seemed to imply that because an engineer has been in the service of public utilities he is not to be relied upon to give honest advice in connection with public affairs. He did not believe this to be true of the great majority of the engineers of the United States. He believed that those who made such an accusation were unworthy of a place in the profession.

E. H. MERRIAM said that every engineer engaged in public work should have in him some element of the salesman with a keen appreciation of the need of educating the public to the necessity and importance of the work which he recommends.

He cited the experience of Dayton along this line. Subsequent to the great flood of 1913, two million dollars was subscribed in order to prevent a repetition of the disaster. Engineering corps were put into the field to make investigations, but the progress was slow and the public, in particular as represented by the newspapers, became dissatisfied. It was decided thereupon to appoint a publicity man, a young engineer with some publicity experience, who would give to the newspapers the facts in the ease. The false impressions were corrected and the public given the information it needed.

R. P. BOLTON said the fact that engineers are engaged in certain lines of commercial work is no bar to their doing independent work and expressing independent opinions, whether they are employed by a municipality or by a private corporation or person. He objected strongly to various reflections throughout the paper, such as that on the work which has been accomplished by large business interests in this country and the suggestion that they should be limited to a certain kind of fame, and that no other credit be given to them. Nor did he see why the author should reflect on the engineers employed by financiers of that wonderful electrical industry which has set the highest standard of engineering of any other industry. The suggestion that our Society should take part in recommending or suggesting the names of engineers for appointments to municipal employment is one that has been considered adverse to the policy of our own and other societies, but a number of societies, including the leading ones, have urged the appointment of engineers as members of Public Service Commissions. Why was not that done in this city? Because the lawyers, who have swallowed practically the whole of the political positions in the State and the city, are afraid of engineers. They do not recognize what an engineer is and what he stands for. The conspicuous and highly talented lawyer who was at the head of the Government at that time stated that he did not appoint engineers because they were always technical, and in his opinion a lawyer could always grasp enough of engineering matters to understand a technical question. He did not believe that the best class of engineers could be brought into the position of taking office under municipal conditions as they are here today. However, he did agree with the author in saying that engineers as a body should take a greater interest and a greater part in municipal affairs; and with Dr. Humphreys and others in saying that engineers will not do their full duty until they recognize the fact that they are not only engineers but are citizens.

H. S. PERSON¹ presented a written discussion, taking up various phases of the subject of Mr. Cooke's paper. He said, among other things, that nowhere had he heard a cleaner-cut, more challenge-like utterance in this great movement than that of the author's. Mr. Cooke has been to the frontier on scouting duty, so to speak, and now returns with his report. It is at the same time an entreaty and an exhortation for the main army of his professional associates to lift up their eyes to see the problem, the opportunities and needs which he has seen in municipal administration, the field for public service particularly de-

¹ Ames Truck School, Dartmouth College.

manding the expert knowledge of the engineer. The response should be in the form of definite plans.

These plans must embrace two main lines of operation, education of the public and of the profession. The public needs education concerning the capacity and adequacy of the engineering profession for public administration; the engineering profession, paradoxical as it may seem, needs to educate itself concerning its incompleteness and inadequacy for that service.

For such self-education, the essential requirements are two: the breaking away from the attitude of mind molded by the motive of private gain and the achievement of one molded by the motive of public service; and the development of the special science of municipal engineering. The municipal engineer must be a composite of engineer, economist, educator, accountant, statistician, executive and administrator.

In furtherance of the second phase of professional education, he agreed with the author as to the wisdom of devoting a section of the library to a Municipal Reference Library.

CHAS. DAY sent a written discussion in the course of which he said: It does not seem possible that our membership should do otherwise than accord the fullest support to those measures which will bring about the highest professional standard in the field of municipal engineering. To-day we occupy the indefensible position of permitting without protest the perpetration of obsolete, inefficient and extravagant methods with regard to municipal work involving the expenditure of millions of dollars. It seems to me that it is entirely incompatible with a proper code of ethics that we should tolerate the continuance of such abuses without giving voice to a strenuous protest. Of course, in the final analysis little progress will be made until engineers, possessing not only the requisite experience and knowledge but a deep interest in public welfare, are willing to accept municipal posts. This pertains in particular to those functions which are generally assumed by city governments, such as street cleaning, removal of ashes, highway work, etc. Probably very few of our members are engaged upon such work.

There is, however, another great field of activity closely related to municipal work which engages the attention of a large number of our members, in the work of public service corporations. Owing to the enactment of laws providing for regulation, public service corporations in many states occupy a position in relation to the public that imposes quite as great obligations as those devolving upon the departments or individuals who are engaged upon purely municipal work.

There can be no doubt that there is justification for the dissatisfaction concerning the results which in many cases have been secured through State regulation of privately operated public utilities. Certain of the men responsible for the policies of such corporations have lacked almost entirely that recognition of the public interest which is referred to by the author.

It may be that in most cases the responsibility for this condition rests directly upon men who are not members of our profession. Nevertheless, this does not relieve us from the duty of asserting ourselves with a view to placing the

businesses to which we are the principal contributors, upon an inherently sound and permanent basis.

There can be no doubt that the type of engineer desired by the author will see that justice is done to corporation and public alike through a frank and unbiased consideration of the apparently conflicting conditions. The qualifications which in Mr. Cooke's judgment are necessary upon the part of the municipal engineer, are equally imperative for those who administer our public service corporations, and it seems to me that this Society can do no more important work than to encourage this spirit in every way within its power.

CARL SCHWARTZ disagreed with the author in his references to the difficulties in securing the professional services of engineers for municipal work, and said that he could personally furnish the names of prominent mechanical and electrical engineers not affiliated in any way with large manufacturing or conflicting interests.

The success of engineers in private enterprises is largely due to the fact that financiers have appreciation and knowledge not alone of the professional standing, since a financier is readily able to measure ability by economic results. To secure such results the engineer must not alone be a scientist, as without a good dose of business judgment he would be unfit for any leading or responsible position.

Admitting that the municipal field may not so far have sufficiently attracted the attention of the engineering profession, he thought that the cause and remedy for this condition are hardly to be looked for in the author's paper. He would refer the author to Bryce's American Commonwealth, and specifically the chapter on why the best men do not go into politics, for a perhaps more reasonable explanation. While the author does not claim that the engineer who holds a public position is in politics, still he advocates the value of advertising, and the writer objected to such publicity methods. In his opinion it would be a calamity should the engineering profession accept the suggestions contained in the paper as a guide for the important field of municipal engineering.

ALEX. DOW was in agreement with previous speakers who contended that the services of experienced men unbiased by affiliations detrimental to the best interests of the municipality could be secured for municipal work. He referred particularly to those experienced in the use of concrete, in the use of asphalt, and in the electrical industry. He believed that in none of these fields would any leading man fail to give a truthful answer to inquiries or to render a signed report that was strictly honest, provided his time and engagements permitted him to accept such a commission.

NEWTON D. BAKER¹ wrote that there are one or two thoughts suggested by Mr. Cooke's paper which he desired to emphasize. In the first place, the difficulty in having engineers with the public point of view has not been entirely with the engineers. Our American cities have not made city engineering a career in the German sense of that word, and, therefore, men who have entered the city's

¹ Mayor of Cleveland.

service and become proficient find the rewards of their professional activity greater in private employment. They soon reach the highest compensation and official dignity possible, and not unnaturally, are unwilling to arrest either their own development or their own progress by staying in the public service. This situation arises from various causes. Our American cities have only recently come to a realizing sense of the importance of accurate and expert service for engineers. The old theory was that a man who devoted half of his time to engineering and half of his time to politics was a better public servant, or at least more entitled to the job. As a consequence of this the public have regarded their engineers as political placemen and have not been willing to sanction the payment of salaries at all in proportion to those paid by private employers. Before we can expect the engineers as a professional body to change their attitude therefore, we must have on the part of the people a perfectly frank understanding that high-grade professional service cannot be expected out of a charitable impulse, but must be compensated in a dignified, adequate way by the public as an employer, and that men of real ability will not accept the public service if their continuance in it is to be interrupted in the midst of useful work on their part by the mere accidents of political change in the headship of city governments. He made these comments not because he did not think these changes are coming about, but because he thought in justice to the engineers the entire fault should not even by inference be assumed by them, and because he was very anxious to have the people of our American cities realize their share of the burden in securing efficient and high-grade service from experts.

ROBERT B. WOLF made a strong plea for the engineer in public service. He believed that the engineer was destined to work out the great social problems of the world as well as the industrial problems.

The word "politics" must be made to have a new meaning and the duty of the engineering profession is to make it synonymous with the highest kind of idealistic service. The reason the world must look to the engineer for a solution of these problems is that in the very nature of things his idealism is practical. His grasp of material facts and laws insures an idealism which is workable, and for this reason will be progressive in its accomplishment of social and political reforms. The fundamental, basic reason why we cannot hope to solve our social problems through our strictly religious and ethical institutions is that they are made up largely of men who have little knowledge of natural sciences. While it is true that the higher spiritual laws include the lower and material laws, it is quite true that we cannot hope to use those higher laws intelligently until we first master the lower. It is because it is the engineer's business to know and use the forces of nature that he, above all others, is qualified to solve the great vital problems of our municipalities.

F. W. TAYLOR wished to correct the impression that might result from the remarks of the previous speakers that the author considered the consulting engineers of the country, and particularly the electrical engineers, disqualified for

consulting work for our municipalities because of their employment by the great public service corporations. Careful reading will show that the author does not say this. The author says that he had been unable to obtain the services for the city of Philadelphia of prominent electrical and consulting engineers. This is a statement of fact, for the reply of these gentlemen was, "We are retained by the public service corporations, or are affiliated with the electrical corporations and therefore not in a position to give you the advice which you seek." It is no reflection either on the integrity of these men that they were placed in a position where they could not give their services to the city of Philadelphia. If there is any reflection at all it passes back to the owners of the companies, who in nine cases out of ten are not engineers, but are financiers who believe that if the cities secure the knowledge to regulate rates, it would ultimately be to the detriment of their companies. This view on the part of the companies, Mr. Taylor did not agree with, since a thorough knowledge of the facts on the part of city officials might as readily lead to a rise as to a decrease in rates.

CHARLES WHITING BAKER said that up to a comparatively recent date cities had been rich mines to be exploited jointly by the politicians and by the franchise-owning companies. Now the public is learning that our city governments may be brought up to the standards which have prevailed for many years in England and in Germany by taking advantage of the skill and ability of the engineer. Within the last five years there has been started the most hopeful movement for the betterment of city government service that has ever been undertaken in this country. He referred to the so-called city manager plan of municipal government. This was begun by the city of Staunton, Va., five years ago and there are now some two dozen cities in the United States which have established the office of city manager and have put engineers in charge of the work.

Besides this, it should be noted that in some other cities which have not formally adopted this plan, engineers are taking a leading part in municipal administration. The author of this paper is practically the city manager of Philadelphia and holds the most important position in municipal service of any engineer in the United States.

ROBERT S. WOODWARD¹ wrote that he was interested to observe that many of the ideas which Mr. Cooke has brought forward are similar in their import to ideas he had long held. To some of these ideas expression was given in an address read at Wood's Hole in July last at the dedication of a new laboratory of the Marine Biological Association.

He was especially interested in what the author had to say in regard to the necessity on the part of the engineer of going somewhat into politics, in the better sense of the word. Before we can bring about the reform essential to further progress in society the engineer must take a hand at the problems presented. His points of view and his methods must be availed of more and more by society if we expect to make evidently needed progress.

¹ President, Carnegie Institution, Washington, D. C.

THE NEW CHARTER FOR ST. LOUIS

BY EDWARD FLAD, ST. LOUIS, MO.

Member of the Society

On June 30, 1914, the city of St. Louis by a majority vote of the citizens adopted a new charter in which the engineering profession is given unusual recognition. The charter provides for a Board of Public Service composed of a president and four directors and specifies that the president and two of the directors "shall be engineers of technical training, of at least ten years' experience, and qualified to design as well as to direct engineering work." The members of the Board are appointed by the mayor and will each receive a salary of \$8000 per annum.

The Board of Public Service has charge of all engineering, construction and reconstruction work undertaken by the city and exercises supervision and control over (a), the department of public utilities, including the waterworks and city lighting; (b) the department of streets and sewers; (c) the department of public welfare, including the divisions of health, of hospitals, of parks and recreation, and of correction; and (d) the department of public safety, including the police and excise divisions when so permitted by the State, the divisions of fire and fire prevention, of weights and measures, and of building and inspection.

The members of the Board are appointed for a term of four years and are subject to removal only for cause. Each director is given charge of a particular department under the general control of the Board.

No ordinance for public work or improvements of any kind or repairs thereof, shall be adopted unless prepared and recommended by the Board of Public Service with an estimate of cost endorsed thereon, and the Board is given authority to let all contracts for public work.

The charter provides for a measure of popular control by the initiative referendum and recall. All city officers and employees except those specifically placed in the unclassified service are appointed and advanced under the merit system controlled by an Efficiency Board composed of three members appointed by the mayor. A single legislative body is provided composed of 28 members elected from districts, and a president elected at large. The only other officers elected are the mayor and comptroller, all others are appointed either by the mayor or by the heads of departments or divisions.

The new charter replaced the one adopted in 1876. The Board of Public Service replaces the Board of Public Improvements provided by the old charter, with added duties and responsibilities.

The city of St. Louis has been singularly fortunate

in having its public work controlled in the past by a board of six men, the majority of whom have always been engineers, although the charter required only one of the members to be an engineer. The provision in the new charter requiring three of the five members of the Board of Public Service to be engineers is a recognition of the valuable services rendered in the past by the engineer members of the Board of Public Improvements. The writer was a member of the board of 13 freeholders by whom the new charter was prepared.

THE ENGINEER AND PUBLICITY

BY C. E. DRAYER,¹ CLEVELAND, OHIO

Non-Member

So far as we know, the first instance of systematic publicity for the engineer and engineering is the work so successfully accomplished by the author of this paper for the Cleveland (Ohio) Engineering Society. This led to the presentation of the paper of which an abstract follows and in which the author first raises the question as to what interest publicity may hold for the engineer. In the first place, the public is deeply interested in the things we are doing. People are glad to know not only of the advance in science but also about the men who make it possible and to give credit where it belongs. If then we can make use of publicity with the definite intention of placing the engineering profession in a higher position in the vision of our employer, the public, a point of interest has been found.

In the second place, we find an opportunity and duty to render service to the public by giving it dependable information about technical subjects. The ordinary newspaper uses the same reporter to write crime, politics, sport, invention, and technical achievement. An editor of one of our Cleveland papers once gave us as his opinion that one reason why news of an engineering nature does not get into the daily papers is because the ordinary reporter has not the technical knowledge to handle it. News, it must be remembered, is nothing more than ideas and facts put into interesting reading.

Here, then, are the two elements of a bargain. The public and the engineering profession have something to exchange and both sides will receive substantial benefit. The engineering profession will find itself in a better position by having the public appreciate the important service it is rendering; the public will find itself deeply interested in the information we are able to give, because it advances public welfare.

¹ Chairman, Publicity Committee, Cleveland Engineering Society, Chamber of Commerce Bldg.

Abstract of paper and discussion presented at the Annual Meeting, December 1914. Complete paper may be obtained without discussion; price 5 cents to members; 10 cents to non-members.

PUBLICITY WORK IN CLEVELAND

In the publicity work of the Cleveland Engineering Society, which has extended now over a period of two years, our first step was to get acquainted with the managing editors of the two leading papers in the city. They were told that the Society had about 500 members, many of whom are at the head of large undertakings on which the growth and prosperity of the city depend, and that the Society stood ready to co-operate with them in obtaining such engineering news as would be of interest to the community.

It so happened that the outgoing issue of the Society's Journal contained the report of a special committee on technical education in Cleveland. Naturally, a large number of people in the city were interested in what engineers had to say about their technical schools. Abstracts to make about three-quarters of a column were written, ready to set in type, and were handed to the editors of the two morning papers. They were printed without alteration. A third paper printed its own abstract and an editorial. If the committee had something to say which the public would be benefited in knowing, surely 200,000 papers with authentic information were a better medium than the 1500 copies of The Journal read largely by technical men.

Another subject of great interest to the public, although it might not appear so from the title, was discussed in R. H. Fernald's paper on The Relation of the Gas Producer to Low-Grade Fuels and Concentration of Power at the Mines. When an abstract appeared in the paper on the Sunday following the lecture, it was headlined as shown herewith:

PRODUCER-GAS TO ELIMINATE SMOKE AND SAVE FUEL

**United States Engineer of Mines
Tells Local Society of
Broad Conservation
Plan**

MILLIONS OF TONS OF COAL WASTED YEARLY

**Production of Gas at Mines From
Coal Now Unmined Would
Solve Problem**

the Cleveland Engineering Society will bear out the assertion that the headlines do not exaggerate the statements made by Dr. Fernald. Our task was merely to make news of plain facts. To the citizens of any large industrial center like Cleveland, smoke elimination and fuel conservation are mighty live questions. News, as was said before, is the turning of facts and ideas into interesting reading.

Probably the largest service to the community performed by the publicity committee of the Cleveland Society was the publishing of 14 inspirational articles by prominent local engineers on Engineering as Life Work. The articles appeared on successive Sundays in the magazine section of a local paper. Beneath the title of each was an editor's note stating the purpose of the series and that they were published under the auspices of the Society. Among the contributors were two past-presidents of The American Society of Mechanical Engineers and a past-president of the American Railway Engineering Association. The theme of the series was to tell the young man about to choose his life work what is before him in the various branches of the engineering profession. Besides appearing in the local paper, most of them were published in the Scientific American and the Case Tech, the student publication of Case School of Applied Science. Some appeared in other periodicals over the country. A young immigrant wrote to one of the contributors and asked for permission to translate his paper into French and Russian to send to those countries.

While we might multiply instances like the above where our work was distinctly a service rendered the public, we shall pass to an enumeration of the tangible benefits to the Society and to the profession growing out of the publicity work.

A higher standing in the estimation of the people and of those in authority in the affairs of the community is one gain. In Cleveland, the coöperation of the Society is usually sought in the solution of questions of public welfare where engineers are qualified to speak.

To cite an instance, the Civil Service Commission early in the present year asked the Society to assist it by taking charge of the preparation and marking of papers for engineering positions. The first request was for 10 examinations, and the results to both the Commission and to the Society were very gratifying. The Commission secured the service of experts at no cost to the city, but which were worth more than it had available funds to employ. The secretary of the Commission told us that the candidates were satisfied with the fairness of the examination. Concerning previous examinations complaints have been made that proper relative weights had not been given to experience and theoretical training. Our publicity committee saw to it that the public learned through the newspapers of the arrangement between the Civil Service Commission

and the Engineering Society. Credit was given where it was due.

Somebody has said that the public is unreasonable only when it is uninformed. It is hardly possible that any sudden gust of public disapproval would arise where engineers are concerned if the public felt that it was well acquainted with them. When the local society engages in publicity work, a revival in the interest of its members in the activities of the society will be apparent. The indifferent members find they have some pride in their society when its activities, of which they approve, are described in the daily paper. It is said on good authority that the publicity campaigns undertaken by Memphis and Des Moines, to present to business men their advantages for a location, resulted in a renewed city spirit equal in value to the new business acquired.

Due largely to the publicity work, there has been a substantial increase in percentage of attendance at the meetings. One estimate was 15 per cent. To stimulate attendance, the committee furnishes the papers advance notices of the meetings, consisting of a picture of the speaker and some 150 words of text telling about him and his subject.

During the last two years some 250 new members have been added to the roll, an increase of over 50 per cent in a society past 30 years old. Of course, it is difficult to say just what per cent of increase in an organization recently very active in all its functions may be credited to publicity work.

It is possible at this time to know only the general nature and approximate limits of publicity with any degree of accuracy. We can, however, enumerate the various channels by which information of an engineering nature may be placed before the public. It is also possible to give approximate relative values to them. In the matter of choosing mediums we are inclined to lay down this broad general principle: When one man has something to tell another, the telling of which will do them both good, he may employ the most direct honorable means. It may be either the written or spoken word.

Under the written word we would include newspapers, periodicals, such as national magazines, and pamphlets. The spoken word would be confined to a rather narrow field and would consist for the most part of talks by engineers before high school classes, classes in Y.M.C.A.'s, lectures before clubs, at special gatherings in churches and the like.

We have shown that the public and the engineering profession are in a position to make an exchange at a profit to both parties. A record of results in one locality where it has been tried points to what may be expected through cooperation in a larger field. Mediums of exchange have been discussed. There remains yet to be suggested a preliminary plan by which systematic and effective work may be done.

Inasmuch as all the profession will share in the bene-

fits of a closer relation with the public, we assume that the efforts of all should be united on a common ground. More definite plans may be worked out by representatives of leading national engineering organizations at such a time and place as is deemed best. In general we believe that the local society working in cooperation with a central national organization will produce the most satisfactory results.

DISCUSSION

A. J. HIMES in a written discussion stated that publicity should eliminate error from the mind of the layman and of the public concerning engineering and thus clear the way for a proper utilization of the engineer's services. Many people are handicapped in their desire to make use of the wares of the engineer because they cannot talk with him familiarly of the things which they desire to do.

It is a waste of time to deny either the need or the value of advertising. But among professional men the subject is hemmed in with so many restrictions that engineers hesitate to make use of such a method of securing business.

Professional men have always considered it proper to reap the advertising rewards that come from their activities in societies and public affairs. It is doubtless true that a paper of unusual value, because of the information that it contains and the excellent work of its author, is much better as an advertisement than a paper of less merit, with smaller chance of adding to the general knowledge, and which may be presumed to be written chiefly for advertising purposes. It is rather difficult to discover the motives which have prompted a man to go to the trouble of writing and presenting a professional paper and no microscopical examination of such motives is worth the effort.

An important error is made when one concludes that legitimate professional advertising is limited to the writing of a paper.

The profession suffers from certain misconceptions of its patrons, including the public, from among which I will enumerate four as follows:

First: It frequently happens on some important work that the preliminary estimate of cost is exceeded in the construction. For this the engineers are roundly denounced. The truth, which never appears in print, is that many such works are completed within the estimate; that where the estimate is exceeded, the cause is frequently a change in plan or increase of quantities for which the engineer has no responsibility whatever; in other cases estimates are stated by men in authority to contain provisions which have not been included; and on some occasions the difficulties encountered are beyond the powers of human foresight.

Second: There is frequently an unreasonable demand for the beginning of construction immediately after an appropriation is made without any regard for the necessity of first making surveys and plans. Of this the Panama Canal was a notable example. The evils attendant upon such a course need not be pointed out to engineers.

Third: Bombastic and unwise laudation of engineering achievement has developed a popular idea that engineering is mathematically precise. In court and before legislative bodies engineers of prominence are sometimes led to declare their ability to determine by formula and with precision

things concerning which it is only possible to make general deductions. Stresses in rail joints may be cited as an example.

Fourth: In the general discussion of the government valuation of railroads, the statement has been frequently made by men in the councils of the nation that the opinion of an engineer is incompetent testimony in valuation proceedings except where it relates to actual quantities which he has measured himself.

It is unnecessary to point out the absurdity and injustice of these misconceptions, and the very great injury which results therefore to the whole profession. The purpose is to call attention to the necessity for publicity, a publicity that will give to the layman a knowledge of our work.

If the public knew that plans once made are seldom changed without increased expense, it would be demanded of its servants that plans should be made in accordance with the original estimates and then carefully adhered to. It would become important that the first estimate should be right, and that when exceeded the reason therefor should be sound. If it were recognized that some things, as, for instance, rail-joint stresses, were beyond the powers of mathematical analysis, engineers would not be condemned because such stresses have not been figured; or that engineers had followed every step of construction work, from the yielding of a pick and the swinging of a maul to the development of the whole program for the construction of a thousand miles of railroad and the cost accounting therefor, then no judge or statesman could make the public believe that the best results in valuation could be secured without free use of engineering experience.

The public mind can only be disabused of these misconceptions of engineering work and the people be supplied with correct ideas of the possibilities and the limitations of engineering art, by publicity.

The mass of rubbish published every day in the newspapers is an appalling evidence of the paucity of worthy thought among those who cater to a need for information. The country is burdened with the wasteful and wanton exploitation of engineering skill. It is time for the profession to assert itself. Engineering projects of public importance should be passed upon by the engineering societies.

Every medium at the command of the engineer should be used and correct information about engineering work placed before each citizen. The profession should be made familiar to all who have an interest therein, and it is rightful to expect that the increased respect and confidence arising from a more intimate knowledge of such work will greatly enhance its material prosperity.

Coöperative advertising by engineering societies conducted on broad lines for the benefit of the public and so as to put the profession on a more substantial basis, is an aim that is worthy of the highest traditions of this Society.

H. McDONALD in a written discussion stated that the engineers of Cleveland were fortunate in having among their number one who in addition to his engineering skill, possesses the taste and willingness to clothe bare technical facts in such garments that they challenge popular attention and interest. If each community were equally fortunate, publicity on engineering matters would be easier.

Few engineers possess this gift or the willingness to de-

vote their time to the task. Many are quite decided in their opinions that there is no need of publicity. They proceed upon the well established theory that virtue is its own reward, and are usually compelled to content themselves therewith.

The writer strongly advocates the participation by engineers in public affairs. They are qualified to guide public policy in matters where their training is of value, but as a class, they have so far failed to convince the public that such is the case.

Their position as a class has been that of an instrument in the hands of other men, who have made a specialty of the study of mankind rather than physics. If engineers can master technical details, they can also learn the laws that control human actions. Recognition is not to be altogether obtained by keeping ourselves and our work before the public in newspaper columns, but by earnest and effective work as organized bodies in every community. That work should consist of watching carefully the manner in which the public affairs involving engineering are administered, taking vigorous organized action looking toward the stopping of the waste of public moneys and graft, and the shaping of legislation involving engineering and industrial matters.

The public should be convinced that we are willing to aid in the proper adjustment of such matters and to give, without selfish motive, sound advice on matters of public policy and the opportunity will not be lacking. A reputation for fearlessness and honesty must be reëstablished and maintained.

Instances are not lacking where professional opinions have been subordinated to the demands of commercialism. Public officers of to-day have difficulty in finding engineers upon whom they can rely for unbiased advice on matters in which organized capital is affected. To merit and obtain confidence engineers must be willing to tell the truth under all circumstances.

It is only such a professional reputation which warrants engineers in making themselves the sole arbiters in preparing specifications, and to preserve that reputation its requirements must be lived up to.

CHARLES WHITING BAKER said that the engineer needs to learn the lesson which is taught by this and Mr. Cooke's paper, of the value of publicity. If the engineer wants to get support for what he is doing, he must know how to reach the ear of the public in the right way. He spoke of the valuable service which had been rendered the street cleaning department by Colonel Waring, who was an engineer. One of his first steps was to put the street cleaning department into white uniforms. The publicity went all over the country and made the department known as it had never been known before and gave the employees a new respect for themselves. This is an instance of what a proper appreciation of publicity may do in a wise engineer's hands.

E. H. WHITLOCK said that it had been his good fortune to watch the results accomplished in Cleveland by Mr. Drayer during the last two years and that he could heartily commend the work done there. Publicity can be differentiated from advertising. It meets the demand on the part of the public for information as to engineering facts, and who can give this better than the engineer?

CALVIN W. RICE thought that it might interest the members of the Society to know that special pains are being taken along publicity lines. Over 60 technical and daily papers in the United States are given copies of everything that we publish and have read at our meetings. In addition special work had been done for this meeting and one of the papers had published over a column in every issue this week.

THE AUTHOR said that the correct test of publicity was the results obtained. Any plan of publicity must be consecutive, it must continue for a period of time. Enough material has been presented before the Society at this and the session of Wednesday evening to occupy the time of a good publicity man for six months. He must, however, work from the standpoint of the newspaper man. Journalism is a profession; it seeks to give the public knowledge that the public wants. Engineering information must be given to the public on a definite plan, otherwise the newspapers will not give us much attention.

SNOW REMOVAL

A REPORT OF THE COMMITTEE ON RESOLUTIONS OF THE SNOW REMOVAL CONFERENCE HELD IN PHILADELPHIA APRIL 16 and 17, 1914.

Early in March 1914, Mr. Morris L. Cooke, Director of the Department of Public Works, Philadelphia, wrote to a number of the leading Eastern cities suggesting the need of a conference on the subject of snow removal and pointed out, that in view of the very apparent lack of engineering methods generally employed in a problem which so clearly calls for engineering study, it might be profitable if those in charge of the matter of snow removal in the larger cities could be brought together, and that at least an approximation of a definite policy of snow removal might result from such a meeting. The suggestion met with such favor that a snow removal conference was held in Philadelphia on April 16 and 17, 1914.

A Committee on Resolutions, J. W. Paxton, chairman, was appointed to submit a report, which would be the result of papers, discussions and recommendations made at this conference, and the Committee makes the following report:

The problem of snow removal must obviously be considered differently in different cities as its solution is dependent upon such variable elements as climate, population, width of streets, density and character of traffic, location of sewer systems, available disposal places and other local conditions, to say nothing of the financial policy of the municipality.

It would seem impossible to formulate anything but

the most general suggestions, and yet it is found that even so vital a matter as the financial policy does not affect the main problem, except in the extent of the work.

The work of snow removal is generally done by contract under the supervision of city officials, payment being made according to the quantity removed as tallied by wagons hauling to the disposal dumps, the forces and equipment consisting of men with shovels, horses and wagons. In some cities, scrapers and plows are used to push the snow to the side of the street, relieving traffic and making it easy to pile, or to load without piling.

Salt is generally and very extensively used for the removal of snow in Liverpool, London, Paris and other European cities. The very general practice is to broadcast coarse salt on the streets during and immediately after a snow storm, and when the snow has been reduced to slush by the action of the salt, the streets are flushed with water and the slush washed down the sewers; but in those cities they do not have very heavy snows and it is doubtful whether it would be practicable here where we have a much greater depth of snow. There is also very serious objection to the use of salt by the Societies for Prevention of Cruelty to Animals and in some of the cities it is prohibited by ordinance. It is questionable whether the use of salt has been given a fair trial in this country for the removal of snow and there is little doubt but that it would be useful in light snow storms.

Much thought has been given to the design of apparatus for melting snow and, also, to special machinery for scraping, loading and transporting. Inventors, designers and manufacturers should be encouraged to continue in the endeavor to produce equipment which will render practical and efficient service, but the amount of snow is so variable and the equipment is in use for such a short period of time that it is desirable it be designed to be useful for other work at different seasons of the year.

The problem confronting the public officials is the removal of snow in the shortest time in such a manner as not to interfere with traffic, and at a minimum cost. Therefore, using the method of scraping, shoveling into trucks or carts and hauling to dumps, the length of haul becomes a most important factor and it can readily be seen that the utilization of sewer manholes as dumps, and the sewer system to carry the material to the rivers, is the most economical method which can be devised as it reduces both the haul and the handling to a minimum. The authorities in charge of the sewer systems have, as a general thing, apprehensions regarding the use of the sewer as a snow carrier. The Borough of Manhattan, New York, Bureau of Sewers, however, made experiments during the winter of 1914 which seem to prove that, within certain limits, such apprehensions are ill-founded.

Gas and chemical combinations in the sewers have little effect on the rate of melting. Two cubic yards per minute is the maximum rate at which snow can be shoveled into a 24-in. manhole. Tidal sewers can only be used to advantage when the tide is low, in which case the factors of the ordinary sewer applies. Siphon sewers can be used as well as the ordinary type.

Where difficulty is experienced with an insufficient flow in the sewers, or where the flow decreases or stops, the water plug may be opened in the drainage area of the sewer above the manhole in use, until the volume of water is sufficient to carry off the snow, but it has been found that the most efficient use of water may be had where water jets are constructed in the manholes into which the snow is dumped. The problem of getting the material into the manholes in the least time with the least interference with traffic opens up a field for the consideration of a special form of manhole to be used satisfactorily for this purpose. Pittsburgh and St. Louis both use a special form of manhole.

The Committee gave further an account of the work of snow removal in the cities of Philadelphia, New York, Boston and Scranton, and also of the Public Service Railway of New Jersey, and the Pennsylvania Railroad Company, on which they base the following conclusions:

1st. The plan of organization and the system to be employed should be worked out in advance of the snow season. This preliminary work should involve: (a) a plan of coöperation among all branches of the municipal government; (b) the formation of a skeleton organization composed of all the available city forces, such as engineers, inspectors, time-keepers, laborers and teams; (c) the division of the city into zones and the determination of a definite method of work for each zone. The various members of the organization should be assigned to these zones and the responsible officials familiarized with the duties expected of them.

The character of work to be performed in the different zones may consist merely of the regulation of opening cross-walks and gutters and otherwise generally assisting pedestrian traffic and the run-off of the snow, or it may consist in the complete removal of the snow from the streets. Owing to the general increase in motor traffic and the concentration of business in definite office districts and to the general public demand for increased urban facilities, the present tendency is to increase the scope of the work involving the complete removal of snow from all main thoroughfares and business streets.

2nd. Removal work should commence as soon as the snow has covered the pavements and the indications point to the storm continuing, and should be carried on continuously. This as a prin-

ciple is successfully followed by street railways and by some cities.

3rd. The carrying capacity of the sewer system should be utilized as far as possible.

The use of the sewers which reduces both the haul and handling to a minimum involves two operations: namely, getting the material to the catch basins or manholes, and then putting the material into the sewers. The first operation can best be done by loading into wagons or trucks and hauling to suitable manholes or by the use of scrapers or graders. The problem of getting the material into the manholes in the least time and with the least interference with traffic opens up a field for consideration of the question of special forms and special locations of manholes designed to be used solely for this purpose.

The method of flushing the snow with fire hose into catch basins may have a limited application but it is too unreliable to have any general value as it depends on weather conditions.

4th. When practicable, where there is only a small area to be cleaned, the work should be performed directly by the municipality by day labor. This method of operation is the most flexible and the most easily administered and it obviates the necessity of measurements and checking involved under the contract system. The work can also be performed by day labor in large areas by adopting the following method: The department to advertise and go out into the open market and hire teams to haul the snow for so much per yard, the price to be determined by the department and to represent a fair estimate of the cost of the work and a fair profit. This, of course, would throw the work open to anyone owning one team, or a hundred or a thousand or more teams, depending upon the amount of work to be performed, and would not leave the department dependent upon any one or more contractors. In this method, as well as when the work must be performed by contract system, a method of measurement as simple and accurate as possible should be used. The practicability of having work done by the municipality will depend among other things on the immediate availability of an appropriation. It is essential for the proper conduct of the work whether by day labor or contract that appropriation for snow removal should be made in advance of necessity for the work.

5th. Coöperation should be sought with the traction companies and use made of adjustable plows and sweepers to open roadways adjacent to street railway tracks at the time that the work of clearing the tracks is being carried on.

6th. Effort should be made to obtain the coöperation of the public and to instruct the householders

in the method of the removal of snow from private premises in such a way as to least impede the city's work. Where sidewalks are of greater width than would be necessary to handle the reduced volume of pedestrian traffic, which may be expected after a heavy snow, the snow instead of being entirely cleared from the sidewalk and piled in the roadway should be left on the sidewalk near the curb line to be later removed by the city when opportunity presents itself.

7th. The police force of the city should coöperate with the street cleaning force and the services of patrolmen as inspectors should be utilized as far as possible. The police in particular should give attention to the enforcement of regulation governing the removal of snow from the sidewalks or from a portion thereof.

DISCUSSION

J. T. FETHERSTON,¹ in a written discussion, remarked that New York City has tried almost every method of contracting for snow work, from the area system to the direct haulage method on vehicle capacity basis. Dividing the city into relatively small districts, larger districts and boroughs has been tried, and it would appear that the responsibility and experience of the contractor were of greater importance than the area or district assignments. In other words, an experienced contractor, with the nucleus of the necessary snow removal equipment, as a rule is in better shape to remove snow rapidly and control sub-contractors than is the municipality. More important still, he usually has sufficient control of funds to pay promptly all men employed. It would seem that experience, control of equipment and responsibility are the main factors to be considered, rather than the area basis, for the assignment of contracts.

The statement of general principles contained in the Committee's report would be clarified if the work were separated into these divisions: (1) contract work, (2) street railway assignments, (3) municipal work. Necessarily under each head should be given the plan, and every reasonable contingency covered by the assignment of the most suitable means of snow removal adapted to particular areas, streets or districts of the city under consideration. All municipal departments should be called in to assist the street cleaning division by the assignment of officers for the supervision of contract work particularly, leaving the street cleaning department as free as possible to perform the work for which its own force is best fitted.

As a general comment on the committee report, it is suggested that, if possible, engineers or street cleaning officials should receive from an authoritative source, such as the Society, a summary of conclusions covering:

(1) A statement as to what types of streets should be cleared of snow, and how far the municipality is justified in removing snow from minor thoroughfares at public expense.

(2) A statement setting up the reasonable depth of snow for which a municipality should have equipment available, and in general the time limits within which streets should be cleared, so as to avoid economic loss. Coupled with this, a maximum depth of snowfall beyond which all citizens and

transporting agencies should be required to place their services at the disposal of the municipality at cost.

(3) A compilation of snow statistics for various parts of this country, and if possible a summary of attending weather conditions.

Each city must work out its own salvation regarding snow removal and disposal methods. The problem is so complicated by uncertainty as to weather conditions that no particular method is best fitted for all cities and all conditions.

E. D. VERY¹ in a written discussion pointed out that an endeavor should be made to define the extent to which snow removal should be carried on in a municipality. This definition should not be made in units of mileage or of square yardage but rather in terms of necessity. In this regard the financial policy so affects the main problem as to deserve considerable study, as the extent to which the work shall be carried on depends largely upon the amount of money a municipality can afford to spend. This question must be answered before we may assume that the area to be cleaned has been decided upon and the appropriation of money must be predicated upon an understanding of the actual need in this regard. We should go further and discuss the manner in which funds for the work should be raised. It is suggested that the tax for such purpose should be levied; a part by a general tax and a part by tax on property immediately benefited. Such a method would restrain the indiscriminate demand for unnecessary service for personal benefit.

Whether the work is to be done by contract or by the municipal forces is a question of local condition and must be solved independently by each locality. It is well to remember that where the force engaged in removing accumulations in the street has also the duty of removing the household wastes, the latter item must be considered as of equal importance with the former and the force employed in the latter work must not be reduced by transferring any part of it to the performance of the former. This is especially true when the use of sewers is to be made for the disposition of the snow, as if wastes are not removed they will find their way into the snow bank, and so become a menace in the clogging of the sewers.

For the purpose of supervision, the division of the work into districts is the proper method but to limit a contractor to one district is of questionable value provided the contractor is able to handle more than one district. The fewer contractors on a given area results in less friction, and labor and vehicles are more easily distributed where there is a common interest in the success of the whole work.

Where the work is performed by contract it is well to confine the contractor to the removal of the large accumulations and to employ a municipal force in clearing crosswalks, keeping catch basin inlets open and removing snow from the immediate vicinity of fire hydrants.

If this conference does nothing else but successfully impress the officials in charge of sewers that it is their duty to permit the free use of the sewers for the disposition of snow, it has given ample reason for its existence. Flushing snow into catch basins is not favored as it has not been proven that such work may be practically accomplished without interfering with the necessary use of these devices.

As to the hiring of teams by the city for snow removal.

¹ Commissioner, Dept. of Street Cleaning, New York.

¹ Sanitary Engr., 17 Battery Place, New York.

it is believed that this is a matter of local condition. New York City has had sad experiences in that line.

As to having an available appropriation for this work, the idea of municipal policy today is to suspect the official of not being worthy of trust in the handling of money, so they limit his appropriation to his actual needs and where the amount which he may need is indeterminate, they hesitate in taking any chance of putting an amount in the hand of the official more than sufficient for his needs for fear that he may spend more than is required.

Police assistance would be most valuable and in the matter of enforcement of sidewalk cleaning regulations the police find themselves very busy but moderately successful. An amendment is suggested that cooperation of police magistrates be employed to the end that police activity may be made effective.

W. GOLDSMITH¹ called attention to a statement in the report where mention is made of enlarging manholes for the quick disposal of snow. In the Manhattan experiments it was shown that two cubic yards of snow per minute can be shovelled into a 24-in. manhole and that 2560 cubic yards were dumped into one sewer by means of three manholes in an eight hour day. This seems to indicate that a 24-in. manhole is large enough. Besides, the effect of an enlarged manhole on the pavement must be considered, the majority of defects in street surfaces being due to manholes of one nature or another and it seems that the elimination rather than an increase of these enemies to pavements should be striven for.

F. KINGSLEY pointed out the fact that the same old cart-and-horse methods for snow removal seem to be used that were adopted when the problem became serious some twenty years ago. It is interesting, however, to note the success of the snow-melting device on the Pennsylvania Railroad, because the melting of snow seems to be the most likely path along which improvement can take place.

The cost of fuel to melt snow is only some 15 per cent of cost of handling it under present methods. The basis for this is that a cubic yard of snow as removed weighs approximately 1000 lb. and would require about 200,000 B. t. u. to reduce it to water, allowing a liberal margin over the latent heat of ice. Coal at \$4 per ton provides about 67,000 B. t. u. for one cent in a perfect furnace, or 27,000 B. t. u. with 40 per cent furnace efficiency. At the latter rate the fuel cost for melting would only be 7½ cents per cubic yard or 15 per cent of the present apparent cost of handling it. This does not include interest or labor charges but these ought not to be insurmountable obstacles.

The problem is peculiarly one that mechanical engineers should be able to solve. It appears to be largely a balancing of the cost of heating surface against interest charges, and 1 sq. ft. of heating surface can transmit heat (as demonstrated by existing locomotive boilers) at an approximate rate of 20,000 B. t. u. per sq. ft. per hour. With less efficient but more rapid transmission, twice this rate does not seem impossible. On this basis, apparatus capable of melting 100 cubic yards of snow an hour would require 500 sq. ft. of heating surface. Certainly there is nothing abnormal involved in the provision of heating surface in such amounts as this.

¹ Asst. Eng., Dept. of Public Works, New York City.

One hundred cubic yards of compacted snow appears to be equivalent to about 450 cubic yards of snow as it falls, and in a 3-in. snowfall this amount would cover 500 linear feet of street. The subject obviously seems to be one that is worth consideration by the various cities in the country. It would be interesting to see some thoroughgoing experiments along this line.

THE HANDLING OF SEWAGE SLUDGE

BY GEORGE S. WEBSTER,¹ PHILADELPHIA, PA.

Non-Member

Usually the first processes of sewage treatment consist in the removal from the sewage of the solid matter in suspension by means of screens or by sedimentation in tanks or basins. When more refined treatment is required it consists in the oxidation of the liquid portion of the sewage together with the fine suspended matter not susceptible to settlement. This latter phase

FIG. 1 RATES BETWEEN BULK OF WET SLUDGE AND ITS PERCENTAGE MOISTURE

of the sewage problem will not be considered in this paper.

In sewage treatment, the material collected on the screens and the deposit in the bottom of sedimentation tanks is called sludge. As removed from tanks it is a dark, slimy mass, containing about 90 per cent moisture, and its consistency is such that it cannot be shoveled but can be readily pumped.

Experience with sewage works indicates that upon an average 1000 persons produce 45 tons of dry solid matter per annum. If this were deposited in tanks as sludge containing 90 per cent moisture it would make 524 cu. yd., but if the sludge contained 95 per cent moisture its volume would be 1060 cu. yd., or about double the former amount. In other words, every ton of dry solid matter contained in sludge 90 per cent moisture which is removed, requires 9 tons of water to be conveyed with it, and if the sludge contains 95 per cent moisture, it requires 19 tons of water to be handled.

¹ Ch. Engr., Bureau of Surveys.

Abstract of paper and discussion presented at Annual Meeting, December, 1914. Complete paper may be obtained without discussion; price 5 cents to members; 10 cents to non-members.

One of the most important considerations, therefore, in handling sludge is the percentage moisture which it contains, as this is a controlling factor in its bulk. It is highly desirable to obtain sludge with as low a moisture content as possible (Fig 1).

Discharges of Wet Sludge in the Sea. Large cities located near the ocean dispose of the wet sludge most economically by carrying it to sea in specially constructed tank steamers. The sludge is pumped from the sedimentation tanks to reservoirs on the wharf from which the steamers are filled by gravity. When the boat reaches the dumping ground in the open sea the outlet valves are opened and the sludge diffused in the sea water as the boat moves along.

Depositing Wet Sludge on Land. For cities situated inland such method of disposal is impracticable on account of the transportation charges and they are confronted with the problem of reducing the bulk of the sludge by removing the water, either by drainage and evaporation on drying beds or by mechanical processes such as presses and centrifuges and of handling it so as to minimize offense.

The type of sedimentation tank adopted, the use of chemical precipitants or the opportunity afforded for sludge digestion have a marked effect upon the volume of sludge produced on account of the moisture content. Generally speaking it may be said that chemical precipitation will produce between 20 and 25 cu. yd. of wet sludge containing about 92 per cent moisture from each million gallons of sewage treated; plain sedimentation from 4 to 7 cu. yd. between 87 and 93 per cent moisture; septic tanks from 1.5 to 3.0 cu. yd. between 80 and 90 per cent moisture; and Emscher or Imhoff tanks from 1 to 2.5 cu. yd. between 75 and 85 per cent moisture.

The disposal of wet sludge without prior dewatering may be accomplished by its application to land in several ways. The earliest method used was called lagooning in which case earth embankments were built enclosing an area of suitable land and the wet sludge run into a depth of as great as 10 ft. The clogging of the soil preventing free drainage of the moisture, the scum formation upon the surface retarding evaporation, and the frequent great depth of the sludge, all tend to prevent the sludge from drying.

To overcome these objections and to dispose of the sludge more quickly, it was run upon the surface of farm land to form a shallow layer which would dry in a reasonable time and could then be plowed in and the field cultivated. But the gross nuisance created by the exposure of such large areas of foul smelling sludge led to the adoption of what is called trenching. As practised at Birmingham, England, the trenches were dug about 3 ft. wide and 18 in. below the surface of the soil, the excavated earth forming banks between the trenches so that they can be filled to a depth of from 24 to 30 in. with wet sludge, after which the tops of the earth banks are thrown over the sludge to pre-

vent nuisance from smell or flies. The porous earth absorbs the moisture and later the land is plowed across the trenches and placed under cultivation. This process can be repeated at intervals of from 18 months to two years.

This method is not being used in new plants and is being abandoned in old plants on account of the area required, the interference which is caused in times of heavy storms, the increased difficulty of operating caused by winter weather and the general cumbersome of the method.

Mechanical Processes for Dewatering Sludge. Among the early mechanical methods of reducing the bulk of the wet sludge by dewatering was pressing in machines which consist of a number of cast-iron plates generally 9 sq. ft. in area with corrugated faces and surrounded by a machined rim so that when placed together they form water-tight cells 2 in. thick. A central pipe about 6 in. in diameter extends through the middle. Over each plate a canvas cloth is placed and sludge forced into the press and subjected to a pressure of from 60 to 75 lb. per sq. in. This squeezes the water out and the resultant cake contains between 50 and 65 per cent moisture and is about one-fifth the bulk of the original wet sludge.

It is necessary to add to the sludge before pressing from $\frac{1}{2}$ to 1 per cent of lime, the fine particles of which facilitate the passage of water, the dissolved lime agglomerating the solids of the sludge.

Another mechanical method of dewatering sludge is by means of centrifuges which occupy less space than presses and do not require the addition of lime to the sludge. Such machines are continuous in action and the work of extracting the moisture consists of two distinct and constantly repeated periods. During the first period the wet sludge is introduced into the machine and by the action of centrifugal force the moisture content reduced. During the second period the sludge thus partly dried is automatically ejected. The final product contains about 60 per cent moisture and occupies about one-eighth the volume of the wet sludge.

Digestion of Sludge. In the methods of sludge handling above described efforts were directed toward preventing the dissemination of the foul odors from the wet mass. Within recent years much thought has been given to devise processes of treatment by the digestion of the putrescent matters to produce an in-offensive sludge both as withdrawn from the tanks and during drying.

One of the methods to accomplish this purpose is to remove the freshly deposited sludge from the sewage sedimentation tanks at intervals and place it in separate tanks. Usually a scum forms upon the surface beneath which more or less active fermentation and decomposition develops. New sludge is added and digested sludge withdrawn from time to time and placed upon underdrained sand or cinder beds for dry-

ing. On account of the digestion of the sludge it dries more rapidly and is much less offensive than fresh sludge.

For the last 20 years it has been known that the retention of sludge in the tank in which it is deposited, which is known as the septic treatment of sewage, resulted in the reduction of the bulk and offensiveness of the sludge, but experience showed that while the sludge was benefited, the water leaving the tank, known as the effluent, was seriously fouled by the decomposition of the organic matter in the sludge.

The separation of the digesting sludge from the settling sewage was adopted with certain modifications by Dr. Imhoff of Essen, Germany. Two-story tanks of this type are known as Emscher or Imhoff tanks. Their extensive introduction in Germany and America is due to the fact that when properly operated they efficiently free the sewage of its settleable solids, yield a fresh inodorous effluent, produce sludge that is inodorous, of low water content and consequent small bulk.

The principles involved in the construction of the Emscher tanks are shown in Fig. 2. The sewage to be settled flows longitudinally through the tank in the cross-section marked *A*; the solids which settle upon the sloping bottom *B* slide down through the slots *C* into the sludge chamber *D*. The gases of decomposition are prevented from entering the upper chamber by the gas baffle *E* but find free exit through the sides at *F*, in which also a scum forms. A pipe *G* extends from the bottom of the sludge compartment to the outside. A quick opening valve at *H* located at a distance of over 3 ft. below the water surface in the tank permits the discharge of the digested sludge by hydrostatic pressure without any pumping. The sludge is placed upon the drying bed, which is composed of a layer of fine sand supported by a layer of cinders or pebbles and underdrained by the tile.

Dried Emscher sludge is suitable for filling low land or use in agriculture, particularly in lightening heavy soils, as it is very spongy in texture due to the entrained gas. But experience has demonstrated that the use of air-dried sludge from any source will not give results comparable with those obtained from the use of artificial fertilizers.

Recovery of Ingredients from Sludge. Sludge contains ammonia, phosphoric acid, potash, grease and carbon. Generally speaking these ingredients are more costly to recover than they are worth. It has been estimated that the manurial value in the excreta of one person in a year is \$2.62, but in the dilute sewage of America this would be contained in about 36,000 gal. of water. If this material is deposited as sludge of 90 per cent moisture it would weigh about 1720 lb. per cu. yd., and each cubic yard would contain only about 80 lb. of organic matter, of which only a part has any monetary value.

The problem of recovering the valuable ingredients

in sewage sludge, therefore, involves the use of economical and efficient processes for drying or pressing to reduce the bulk for transportation; also in order to recover the grease in sewage with present methods, it is necessary to have the sludge in a very dry condition.

Where refuse disposal plants and sewage treatment works are located in close proximity to each other, an opportunity is offered for the advantageous disposal of sewage sludge by burning it with refuse.

The most serious part of the problem of sewage disposal is the handling of the sludge which results from every known method of treatment. It is possible that in the future, in order to meet higher standards of hygiene and cleanliness, methods may be devised for

FIG. 2 CONSTRUCTION OF EMSCHER TANK

intercepting sewage solids as near their place of origin as possible, and before they have become offensive, and also to recover practically all of their ingredients which have value prior to their breaking up and in part entering into solution.

This prompt removal of organic matter from sewage will also aid greatly in the prevention of the pollution of the water courses, and will tend to promote the public health and comfort.

In his paper, the author gives data upon several installations in different cities, here and abroad, in addition to the summary of methods of handling sludge which has just been outlined.

DISCUSSION

C. W. HENDRICK,¹ in a discussion of the subject, remarked that the plant at Baltimore is located so that the entire operation is by electricity produced by the flow of the sewage, enabling them to handle the sludge by sludge pumps at a minimum cost. Having this power available, they move the sludge from the separation tank to the digesting tank at frequent intervals before the digestion in the separation tanks becomes a factor.

They deliver the digested sludge at about 90 per cent moisture to their customers by gravity, the wagon driving under

¹Ch. Engr., Sewerage Commission, Baltimore, Md.

the supply pipe. This reduces the cost of delivery to practically nothing. Where the supply runs ahead of the demand, they pass the liquefied sludge to underdrained sand beds, where it is dried and then sold as fertilizer. In this way they are selling the liquified and dry sludge as rapidly as they are manufacturing it.

About 4 cu. ft. of 90 per cent sludge per person per annum are produced in their separation digestion tanks. In their efforts to produce a market for this sludge, they have tried to meet all the conditions of the demand. Some are taking the sludge at 90 per cent moisture, others wish it in the dry state, and others are considering using it as a commercial filler in fertilizers and require about 15 or 20 per cent moisture. By the use of a centrifugal drying apparatus, known as a direct heat dryer, they have been able to extract the moisture down to about 18 per cent.

W. L. D'OLIER said that the author had so aptly defined the problem in his conclusions that he could not refrain from quoting them: "The most serious part of the problem of sewage disposal is the handling of the sludge." Therefore, this part of the problem of sewage disposal is an important feature in determining the method of treatment. "In order to meet higher standards of hygiene and cleanliness, methods may be devised for intercepting sewage solids as near their place of origin as possible." This is a well expressed thought. Means for such methods are available and are more and more recognized and adopted. He referred to fine screening methods. He agreed with the author that an effort should be made to recover practically all of the ingredients of the sewage solids which have value prior to their breaking up and entering in part into solution, which value is lost with the comminution, disintegration and dissolution of the solids.

In referring to the handling of digested sludge, he stated it is the common practice to select sludge beds, which, at the best, are a local nuisance; the working age limit of these sludge beds before they become impregnated is now recognized as a factor and the care and maintenance of these beds must be of a high order. Further, with the growth of our cities and the necessary increase of sewage, increased area is required and the cost of handling of the sludge onto and off the beds must be considered. In our northern climate, we are also confronted with the abandonment of the use of the beds for a term of months during winter which necessitates the additional cost of providing tank storage capacity.

These facts and features existing with sludge bed practice have urged the mechanical treatment of sludge. The results to date show effective work, but first cost, upkeep, and operating costs have been excessive. A rotary sludge filter developed abroad, now being exploited in this country, promises to lessen costs materially, and represents an important step in mechanical treatment of sludge. The speaker said the values are spent in digested sludge. Sludge from fine screens contains its manual values and from tests abroad a net return to the plant can be effected by the treatment of sludge for by products.

THE AUTHOR in closing said that whatever process was used in treating sludge or caring for sludge, it should be remembered that a plant is not automatic and it requires constant maintenance at all times on the ground.

TRAINING FOR CITY EMPLOYEES IN THE MUNICIPAL COLLEGES OF GERMANY

BY CLYDE LYNDON KING,¹ PHILADELPHIA, PA.

Non-Member

This paper is the result of a close study of the educational methods of Germany with special reference to the facilities and requirements for training for municipal service. The paper discusses in detail the reasons for the thorough training which is provided, the various groups of schools and colleges available for the work, the curricula which are followed, and the methods and character of the training. There is a brief review of the facilities in our own country for such instruction and comparison is made of their work with the work accomplished in Germany. In what follows, a summary is given only of certain sections of the paper and the reader is further referred to the complete pamphlet.

Four factors may be singled out as being responsible for the tendency toward sustained and thorough, yet specialized and practical, preparation for municipal service in Germany.

The first is the rapid rise in urban populations. Half of the German population are now urban residents. This enormous increase in urban populations means an increase in public functions assumed by city governments many times greater than the increase in population and requires efficiency and training of public employees.

Preparation for governmental positions in the state has been provided for in the state universities. These institutions are under the domination of practically the same group of officials that control the state administration. Thus, while state positions are amply prepared for, at least in certain of the universities, they do not tend to give the specialization and the emphasis upon municipal service demanded by urban needs, and a demand was created for local institutions that would offer the necessary training for municipal employees. This constitutes the second factor.

The burgomeister and the paid expert advisers in the magistrat were, as a rule, well trained at the state institutions. But no special training was provided for the great rank and file of city employees, the efficiency of whom, after all, decides the skill and utility with which the taxpayer's money is spent. The need for training well every municipal employee through inadequate preparation for positions, is the third factor.

The fourth factor is that public service is a recognized profession of dignity and permanence in tenure. The oft-repeated assertion that there is *no* politics in

¹Wharton School of Finance and Commerce, Univ. of Pa.

Abstract of paper and discussion presented at the Annual Meeting, December 1914. Complete paper may be obtained without discussion; price 5 cents to members, 10 cents to non-members.

German city positions is far from accurate; but in Germany the provincialism characteristic of so many American cities, which brands experts from other cities or states as "outsiders" or "aliens," finds no place. The result is that a public employe with adequate qualifications, who finds himself blocked in one city because of his party affiliations, can look toward employment in other cities. A position once secured, a tenure for life or for a term of 12 or 24 years, is assured, followed by a pension at the end of service. Moreover, promotion is made from city to city so that there is no limit to the economic returns and social prestige of the public official of competence and skill. Even the burgomeister and all the leading expert advisers in the magistrat are chosen at will from other cities. The salary, moreover, is adequate to attract the best talent, and increases in remuneration follow at specific intervals. The national laws frequently provide that appointees to certain positions shall have stated professional qualifications, but all examinations are qualifying and not competitive. The result is freedom of choice by an employing official who must have the best talent and get the best results within his expenditures, for pressure of the tax is as keenly felt in German cities as in American cities.

The fifth factor is the fact that the great public utilities such as the street railways, gas and rail waterways, are publicly owned and operated. This means that not only the best paying positions but also the positions carrying with them social prestige and honor, are within the gift of the state rather than in the power of private corporations. The youth of capacity and training turns, therefore, by preference to the public service.

The technical training required for the municipal expert in Germany is usually afforded by some branch of the regular educational system.

In the great technical universities everywhere maintained by the individual states, technical training of the most definite and specific kind can be obtained for either public or private expert work. At the present time there are 11 great scientific universities, the organization of which is under the control of the several states of the German empire.

Below the highest technical institutions are two grades of machine trade or mechanical engineering schools, those providing for the training of engineers, constructors, foremen, machine draftsmen, etc., and those of a lower grade which train machinists, mechanical draftsmen and technical officials of middle rank and others preparing for positions that require a less highly developed technical ability. To both these classes of schools are often added Sunday and evening courses, open to workmen who cannot afford to give up work entirely and attend school.

Technical preparation for expert work in building trades can be secured in the fifty odd building-trades schools in Germany, most of them with two depart-

ments; architectural (Hochbau) and civil engineering (Tiefbau).

Technical preparation for the industrial arts can be secured in either one of the following groups of art trade schools: industrial continuation schools for the art classes; schools for hand-crafts; schools for industrial art and hand-crafts, and industrial art schools. Preparation for other special positions requiring technical preparation can be found in the continuation schools, in the textile schools, in the technical schools for woodworkers, in the commercial schools, many of which are also supported by the leading commercial and labor organizations of the country, in the modest classes conducted in winter evening hours by the light of the oil lamp in the low school room of the villages.

General school training, however, can not make the efficient employe; for this there must be scientific preparation and, in the case of employes and officials in municipal service, particular training. The author takes up a study of the general educational system for municipal employes, with a discussion of particular institutions, based on an extensive study of catalogues and announcements. Two examples only will be quoted in this abstract, the Akademie für kommunale Verwaltung zu Düsseldorf, and the Erste Preussische Verwaltungs-Seminar zu Aschersleben.

The purpose of the academy for municipal administration in Düsseldorf, opened for work in the autumn of 1911, is to strengthen and broaden the knowledge of and to offer a scientific and practical training to municipal officials, and to give business-like, scientific and practical education to persons intending to enter the municipal service. A survey of the courses offered and the methods employed indicates that the academy is primarily an institution for the further training of the higher municipal officials.

The academy is a municipal institution of the city of Düsseldorf, established by the city council. The teaching staff is composed of (a) official expert teachers, (b) expert teachers who offer lectures for each academic year, (c) honorary experts, who offer lectures for a specified time on unspecified subjects, (d) leading state and municipal officials, (e) scholars and (f) former professional men who are procured for certain discourses. While the academy is thus under municipal control and supported by municipal grants, it is subject to state supervision by the minister of ecclesiastical and educational affairs.

The courses offered include the following subjects: Constitutional rights; governmental rights; the police power; social questions; school and sanitary administration and legislation; insurance law; road law; economics; agricultural economy; political science; sociology; the resources of the country; national economy; the lawful rights of government; the organization of city, state and nation; efficiency in government; the science of finance; taxation law; money and bank-

ing; public works; the city's utilities; statistics; building regulations and administration; the cultivation of prosperity and of refinement; defense of the country; the labor question; relief of the poor; business law; practical work in administrative law; municipal finance and constitutional law; criminal law and procedure; the poor law; administrative law; labor union laws and their interpretation; criminology, hygiene and commercial and financial bookkeeping.

Selective courses are provided, such as one in the science of law which includes the foundation principles as to the rights of citizens and the rights of officials; purchases, leases, deeds and their characteristics; indemnity obligations of the community; earnings and laws of properties; real estate law, rights of mortgages, the authority of parents and the power of the respective governments as guardians; the rights of associations and of business; commercial law; the foundation principles as to state, rural and city administrative law; the constitution of the state of Prussia, the Imperial constitution, the rights of administrative organs of government, the police power and the general position of the police including the safety and sanitary police. There is a course in taxation, one in insurance law, statistics. Thorough-going courses are offered in national economy with special application to the protection of properties and the development of new industrial opportunities. Corrupt practices and efficiency in government are likewise taught as are the cultivation of prosperity in the different communities and the inculcation of the proper doctrines as to a national program for industrial supremacy. In the course germane to pure water for the city are given complete geological data.

Quite in contrast to the Düsseldorf academy, which trains primarily the higher officials, is the Professional Training School for Civil Service at Aschersleben which offers courses preparing primarily for the one year probationary service the middle and lower classes of public employes, and for promotion from a lower to a higher grade of service. The institution is administered by the magistrat of the city of Aschersleben and its stated purpose is "to give to young persons the general and professional education necessary to enter the public service career as a minor or middle officer." The course gives at the same time an opportunity to prepare for higher municipal administrative positions, such as mayors in smaller towns and the higher posts in the larger towns.

The duration of the general course is three years. The school also offers a one year special course for the training of minor civil service employes under governmental, provincial and administrative boards, as well as a one year continuation training course for minor municipal officials. It also provides a three months' continuation course for those in military service who

may desire to prepare during compulsory army service for minor governmental positions.

The curriculum includes three general classes of subjects: (a) scientific courses such as German, mathematics, history, geography, French, English, chemistry and physics; (b) professional courses such as jurisprudence or general legal knowledge, constitutional and administrative law, social administration, political economy, public finances, the science of taxation, the budget and the treasury; and (c) applied courses such as typewriting, stenography, drawing, accounting, bookkeeping, arithmetic and German.

The instructors are employed teachers and the public officials of the city of Aschersleben. At the end of the one year, the tuition for which is 150 M., there is a final examination in the presence of a state examiner, the chief burgomeister of Aschersleben and invited members of the Central Alliance of Prussian officials on the basis of which a final graduation certificate is given.

This survey of what certain German institutions are doing leads to these definite conclusions: (a) While American universities are doing much, they are not offering the practical, definite preparation for public service that is being offered by certain German institutions; (b) that the courses of study offered and the plans for municipal colleges in Germany point to endless possibilities for adaptation in the courses and work being offered in American colleges and universities; (c) to the end that the public employe may be more adequately and efficiently trained, our colleges and universities can extend with profit to themselves and to the public, the number of definite, practical courses offered in their institutions; and (d) particular attention can and should be given to the preparation for special types of public service in certain of our educational institutions. One or two of the universities in the larger cities can prepare definitely for municipal service, others for the consular and diplomatic service, others for state service, others for service in departments of health and sanitation, while others can prepare experts in engineering, social, financial and accounting fields; and (e) there is a need in America for a few special institutions offering a specialized training of and for the public employee, who has had his technical preparation such as is given in the Academy for Public Administration at Düsseldorf and the Seminary for the Public Service at Aschersleben.

DISCUSSION

J. F. YOUNG,¹ in a written discussion, questioned whether courses in municipal subjects should be offered chiefly for the young college student or for the city employe. Hereto-

¹ Univ. of Penn., Phila.

fore we have taken for granted that the young college man was to be the source of our future supply of city experts.

We should work chiefly in the opposite direction, and should so arrange our courses that they will appeal to and help the man who is already active in city employment, or the practising engineer, who after having seen the problem from a point nearer its center, has decided that he wishes to devote himself to city work. Both these types of men are far more valuable for the purpose of providing and training an adequate supply of scientific technical city administrators and experts than the young college student.

A sharper distinction is needed between the general course on city government and the technical highly specialized course on sanitation, housing conditions and methods, city transit, labor, accounting, finance, etc. Thus far we have tried to cover all these fields and have therefore presented in a single course a group of studies which are too general for the technical student and too technical for the general student.

With the new attention to the subject which is now arising, we must have a clearer notion of the class of men and women who are to be trained; a relegation of the general courses to the field of general education of college undergraduates; and a more extensive development of the highly specialized technical subjects for smaller classes of professional men and women. This plan also involves a complete transfer of the technical work to the evening, in order that it may be pursued by those who are already engaged in engineering, municipal employment or other vocations.

Such a sharp distinction between courses, based on a clearer view of the clientele to which they are to appeal, would lead to a different development from that in Germany, but would answer more fully the distinctively American needs for the training of municipal servants.

J. A. FAIRLIE,¹ in a written discussion, stated that the professional schools in this country, in the state and private universities, are giving professional training in engineering, law and medicine, which offers special training for municipal service. In several states there are Associations of Municipal Officials which hold their meetings and carry on their work in coöperation with the state universities. It has been suggested that the university should offer a series of short courses, for a week or two, in municipal subjects, for city officials, similar to its short courses in agriculture.

There is undoubtedly need for further development. This will require the active coöperation of our educational institutions, public officials and the members of the several technical professions.

H. S. GILBERTSON² wrote that there is an academic and practical reason why we have not developed a profession of public service. The academic reason is that there has been a fear on the part of a large number of political leaders that democracy would be endangered by a permanent and highly trained civil service; that we would drift into bureaucracy, and all that it entails. The practical reason is that another,

and a very large element in political leadership, has desired to control appointments to public office for party reasons.

So long as this latter condition prevails, it is perfectly obvious that mere efficiency and fitness are minor considerations, and public service was repellent to men of high qualifications.

Present conditions afford much hope that both the academic and the practical objections to a trained civil service will gradually disappear.

Civil service reform also obviously favors the trained men. The merit system in the civil service was primarily devised as a method of eliminating politics and the most unfit applicants for public office in the lower grades of the service. But civil service reform is developing in new directions and is correcting some of its mistakes. There is a tendency to make records of efficiency the basis of promotion. This undoubtedly will favor not only a higher degree of preparation on the individual's entry into public service, but a certain standard of performance will be made the price of his remaining in the service. This should so dignify civil service that a higher type of men will be attracted to it.

Still another movement which will greatly favor a trained body of public servants is the application of the principle of the short ballot. When it is carried to its logical limits there will be a much sharper distinction made in the public mind between politics and administration.

There is coming to be a general recognition on the part of all intelligent people of the need for better trained public officials. People are beginning to see that when everything else is being subjected to high efficiency tests, government cannot much longer be run on the haphazard plan which has obtained in the past. Also there is the high cost of government. It is impossible to tell what we are paying for unnecessary and ill-performed public service. Senator Aldridge, some years ago, made the statement that \$300,000,000 a year could be saved by the federal government.

Finally, we must consider the growing complexity of governmental functions. It is not simply that we are branching out in new fields, but that we are undertaking in a scientific way to perform old obligations. Police administration, for example, has become almost a science. In the field of corrections we are not content to have jail keepers, but we must have constructive sociologists who know something about the causes and remedies of crime. Likewise, public health administration no longer means stamping out epidemics, but it seeks to eliminate the conditions which may at any moment produce ill health.

SANFORD E. THOMPSON said that in the problem of municipal work we must also consider the demand for municipally trained men. Until our cities realize the necessity for these men and there are more openings for them, there will be very little increase in the education to be offered. This situation, however, is improving, through the appointment of city managers and other steps tending toward the department of municipal work. He believed that the college alone does not offer the training that it should for this kind of work. The student must also have practical experience, and he had found the best men to employ to be those who have done practical work, worked their way through college or done special work in the summer.

A STUDY OF CLEANING FILTER SANDS WITH NO OPPORTUNITY FOR BONUS PAYMENTS

BY SANFORD E. THOMPSON, NEWTON HIGHLANDS, MASS.

Member of the Society

Efficiency in municipal government will come about only as the work in the various departments is put on a basis which gives each man, from the common laborer up to the skilled artisan and clerk, a well-defined task to do in a given time, with a definite reward for its accomplishment. Under the ordinary methods of handling city work it is cheaper where there is fair competition to let work by contract than to handle it by day labor. With an effective system that eliminates not merely favoritism but also presents a definite incentive for each man to do a fair day's work, a city may save the contractor's profit, employ its own force of city men, and avoid one of the largest sources for mulching a city treasury through collusion between the city officials and contractors.

The construction and maintenance work in the department of public works is a field that offers the largest opportunities from an engineering standpoint. It includes such operations as trenching, pipe-laying, sewer construction, aqueduct construction, filter cleaning, street cleaning, road building, grading, concrete work, and building construction. All of these can be handled by scientific methods.

In the present paper one of the accomplishments of the City of Philadelphia along the line of improved methods is described, viz., the cleaning of filter sand, one of the operations in the Bureau of Water of the Department of Public Works, which is in charge of Mr. Carleton E. Davis, Chief of the Bureau, and under the supervision of Mr. Morris L. Cooke, Director of Public Works.

Results Accomplished. The object of the plan has been to lay out the work of each gang of men so as to increase the effectiveness of the plant and provide a definite task to be accomplished in a day.

The results of the plan which is being put into operation are as follows:

Rotation of cleaning the filters is planned in advance by well defined rule.

A definite area of sand to clean is assigned to each gang, this area depending upon the depth of cleaning necessary.

This setting of tasks has increased output of each gang 15 per cent and this should be further increased to at least 25 per cent.

Accurate records are kept, showing the time consumed by each gang.

Cost accounts, as well as pay-roll, are made up from the time tickets furnished to the men.

Gang leaders are required to pay closer attention to their duties.

Improved apparatus and machinery are under consideration.

Methods of determining depths of sand to clean are being standardized.

Obstacles Encountered. The paper contains an account of the methods introduced to secure these results. As indicated in the title of the paper the Philadelphia ordinances prevent the payment of a bonus and thus make it difficult to encourage the men to accomplish the tasks assigned to them. The city fixes the rate of pay of unskilled laborers on a level wage per day regardless of the quality of the workman or the amount of work he can do. Civil service regulation, which prevents the discharge of a man for political reasons, also limits the power of discharge for inefficiency. Although the fear of discharge affords a crude means for obtaining a fair day's work, its elimination, with no opportunity for providing a substitute increases the difficulties. The handling of the work would have been much simplified if it had been possible to provide, for a man well fitted to his work, a reward for accomplishing a good day's task.

At the beginning, the general attitude of the men and the foremen was antagonistic, as is almost always the case where new methods are being introduced. This is gradually overcome as the results become evident.

Method of Attack. The method of attacking any problem in order to place it on a scientific basis varies with the character of the work. In certain cases, such as intricate factory operations, it is necessary, before any tasks are set or even before time studies are made, to establish a complete system of routing the materials and the employees. In other cases the first necessity is to establish standards, making minute investigation of the processes. In still other cases time studies can be made at the start.

In the sand cleaning proposition all of these methods were carried on in a measure simultaneously. Studies were made of the men and the methods employed to see where the manner of handling the work could be improved. Time studies were made to determine the unit times for each individual operation, so that the tasks could be figured accurately in advance. From records already on file, giving the approximate time for cleaning, it was possible to begin the organization of the routing system.

Unit Times. The unit times for the individual operations were determined by the taking of a large number of time studies in such a way as to eliminate all unnecessary delays, but with a sufficient allowance

for resting and delays which were unavoidable. The unit times obtained are given in Table I.

TABLE I UNIT TIMES

Operation	Unit Time per Operation Min.	Time per Cu.-Yd. per 1-in. Depth Min.
Moving hopper.....	0.20	0.34
Moving separator.....	0.50	0.45
Moving hopper hose.....	0.25	0.11
Moving track.....	0.83	0.44
Waiting for hopper to empty.....	0.42	0.38
Moving pressure hose.....	1.80	0.30
Additional necessary rest.....	..	0.12
Shoveling to hopper.....	6.32

The time given in each case is that for the gang, since it was necessary on this work to set a task for the entire gang instead of starting the individual men, as it is always best to do when possible. The time of shoveling into the hopper is in each case based on the rate of output that the ejectors will take care of. It was found that one man, instead of two, could very nearly produce the required output, but this would have lengthened the time of cleaning so as to be inadvisable. For example, with one man shoveling, the shoveling time per cu. yd. is 8.8 minutes with a 1-in. depth, and 6.75 minutes per cu. yd. when the depth is 18 in. These studies indicate therefore that further change is necessary in the method of operation so as to increase the output of the injector and separator in order to obtain the full value of the labor of the gang.

Routing. The routing was accomplished by the aid of a bulletin board of the type used in the Taylor system provided with suitable books for the tickets which designated the work of each man. One of the lines of books held tickets indicating "Work to be done NOT READY"; a second line above it, "Work to be done READY"; and the third line, above this "WORK IN PROGRESS." On these tickets, there is space for all the information required.

Setting Tasks. Having determined the unit times and established the system of routing and giving out of tickets, the area of surface that should be shoveled by each gang was figured and the point to which they were supposed to go in a day's work was marked with a flag. Curves have been plotted, giving distances to clean for the outside and inside gangs for various depths.

On the first two days, after everything was ready, no instructions were given the gang leader or the men as to how much they were expected to do. The total area shoveled by each gang, however, was noted, and compared with the area they should have accomplished. Every gang shoveled less than the figured area, the amount running from 10½ per cent less to 31½ per cent less. After this second day's work we concen-

trated on one gang, and laid out in advance the amount they should accomplish in a day. As a result, they readily accomplished the task and reached the mark. The task setting was then extended to other gangs.

An interesting point came up in connection with the handling of the work at first. The men in the outside bays had to shovel about 7 per cent more sand than those in the inside bays because the areas were wider; nevertheless, all gangs had been accustomed to keep abreast, the men who had the narrower width to handle slowing up to accommodate their speed to the outside men. When the men began working by the task, the inside men, because of the narrower width, were given the longer area to cover and gaged their speed to accomplish their task. The outside men, although shoveling a greater width kept abreast with them without special trouble, thus exceeding their task.

DISCUSSION

CARLETON E. DAVIS¹ contributed a discussion in which was additional information upon the operation of the Philadelphia filters. A few quotations follow:

The labor cost of operating the filters of the Philadelphia water supply is about \$175,000 per year. The result of Mr. Thompson's work as maintained up to the present time is to increase by about 15 per cent the output of the force employed upon cleaning sand in the final filters. This phase of the filter operation represents perhaps 90 per cent of the total labor cost of running the plants. This pick-up is very gratifying to all concerned and the author may well feel pleased that he has accomplished so much in the face of adverse circumstances.

Mr. Thompson's studies have developed a marked advance in the organization of the force and the handling of problems connected therewith. They have not, however, changed the fundamental characteristics of the filtration factors of the plant, nor have any new underlying principles been discovered. This should be clearly understood and the statement that rotation of cleaning filters is planned in advance by a well defined rule should be interpreted accordingly. The planning is done in advance as far as possible, as is the case in all well organized filter plants, but no new rule has been discovered or developed whereby each filter can be assigned to a fixed position in a prearranged cleaning schedule.

The Delaware River from which the Torresdale filters take their water is affected by storms and other weather conditions, by seasonal changes, by temperature variations, by tides, and even by navigation in the stream. A sudden or unexpected storm or any one of a number of other phenomena may upset any prediction as to the exact day when a particular filter should be cleaned.

The sand cleaning groups are now working at increased speed and with less lost time caused by errors or false motions on the part of the foremen. Certain factors stand out more prominently than others in having produced these results. Defining in advance what shall constitute a day's work, clear and easily understood general orders, and the tuning up of the organization whereby each man is more

¹Chief Bureau of Water, Philadelphia

or less on his mettle, appear to be the features productive of the most good.

Time studies were instrumental in determining what is a fair day's work. Experience showed that better results were obtained by clearly marking the limits of each hour's work rather than depending upon a single mark defining the end of a whole day's work. The more frequent goals aid the judgment of the foremen and stimulate the efforts of the men.

General standing orders containing explicit and readily interpreted instructions about each feature of the work are issued to all foremen. These orders place before each man an outline of his duties and take away the excuse of ignorance or misunderstanding.

THE AUTHOR in closing said that he did not agree with Mr. Davis in his idea that the arrangement of the cleaning cannot be designated very distinctly in advance. Studies have been made to a certain extent on the general operation of filters at different plants, with a view of going into this matter but a continuation of study in this line is bound to result in a possibility of planning the different features very definitely and reaching the fundamental conditions which do not appear on the surface.

THE DESIGN AND OPERATION OF THE CLEVELAND MUNICIPAL ELECTRIC LIGHT PLANT

BY FREDERICK W. BALLARD, CLEVELAND, O.

Member of the Society

The new municipal lighting station on East 53rd street, Cleveland, Ohio, went into operation July 20, 1914. It is the largest central station to be built by a municipality in this country, and is intended not only to supply electric current for street and commercial lighting, but also for power users. The rates which are being charged for service range from \$0.03 per kw-hr. maximum to \$0.01 per kw-hr. minimum. This station has a capacity of 25,000 kw. and is at present loaded to one-fifth of its capacity.

The decision to build this plant by the city of Cleveland was the result of experience with a small station of 1500-kw. capacity, known as the Brooklyn Station, which has been in operation by the city since 1906. It had been started by a bond issue of \$30,000 and had by appropriations amounting in all to \$211,649.22, together with additions to its plant from profits and earnings, grown to a total investment in plant value of \$548,182.43. It had thus made the remarkable record of having acquired more than one-half of its total value in eight years from the earnings of the plant itself. Table 1 is a condensed statement of the financial record and Tables 2, 3 and 4 of the revenue and expense from this station.

Abstract of paper and discussion presented at the Annual Meeting, December 1914. Complete paper may be obtained without discussion, price 10 cents to members; 20 cents to non-members.

A close analysis of the figures in the tables shows that in many cases these costs could be greatly reduced by the operation of a system on a large scale, and by the efficiencies which will be obtained in the new power station. The item of cost in central station work which has usually been considered the most uncertain and problematical, and therefore most likely to stand in the way of success for municipalities, is the cost of distribution. The costs for operation and maintenance of the distribution system connected with the Brooklyn Lighting Station in Cleveland, becomes, therefore, of particular interest, and the itemized costs set forth in Table 4 establishes a certain definite value for this feature.

PRELIMINARY ESTIMATES FOR THE NEW STATION

The estimated results which will be secured from the new 25,000-kw. station which has just been placed in operation, are based upon an annual output of 60,000,000 kw-hr., and with fixed charges based upon a total plant investment of \$3,000,000.00. Fixed charges amounting to 9 per cent on this investment would equal \$0.0045 per kw-hr. Cost for coal is estimated at \$0.002 per kw-hr. Station costs exclusive of coal at \$0.0015. Distribution costs, exclusive of fixed charges at \$0.004. Administration charges at \$0.0005 and profits at 8 per cent on the investment at \$0.004. This makes an average price to be secured per kw-hr. generated of \$0.0165. From the three months' operation of this station, together with tests that have been conducted the indications are that these estimated results will be secured.

In explanation of these figures, the author says that it would be conservative to allow for an average interest rate of $4\frac{1}{2}$ per cent on the whole investment of \$3,000,000. The tax rate can be conservatively estimated at $1\frac{1}{2}$ per cent, and the rate to be allowed for a reserve fund for depreciation, or what really would better be known as an amortization fund, since depreciation, obsolescence, etc., will be taken care of from the maintenance fund. The amortization fund should be taken care of by a rate of 3 per cent, this rate for use as a conservative allowance, because 2.92 per cent of the original cost invested annually at 4 per cent compound interest will equal the original investment in 22 years. These rates for interest, taxes and depreciation call for an annual allowance to cover fixed charges of 9 per cent of the original investment.

In order to arrive at the estimated unit cost for the fixed charges, it was necessary to assume a certain total output for the station for a year. A 40 per cent load factor is generally considered very good in central station work. There is no question, however, but that under good conditions a load factor much better than this can be secured. Assuming a 40 per cent load factor in a peak load of 18,000 kw. would give a total output a year of approximately 60,000,000 kw-hr.

Fixed charges for the entire plant investment of \$3,000,000 rated at 9 per cent would amount to \$270,000 per year, and on the basis of a 60,000,000 kw-hr. output the cost per kw-hr. to cover fixed charges would be \$0.0045 or \$0.0015 for the station cost and \$0.003 for the distribution cost.

Other items to be decided upon are unit costs for coal, labor, maintenance and sundries; expense for operation and maintenance of the distribution system; and administration charges. The value of

FIG. 1 EXTERIOR VIEW OF THE CLEVELAND MUNICIPAL LIGHTING PLANT

\$0.0005 for the last item was based on the known cost in connection with the Brooklyn Station. In order to be fair in making a comparison with privately owned and operated plants, an allowance was made for profit of 8 per cent, or \$0.004 per kw-hr., as mentioned above. The several unit costs are given in Table 5.

TABLE 5 ESTIMATE ON UNIT COSTS FOR EAST 53RD STREET STATION

STATION COSTS		COST PER KW-HR.
Coal		\$0.002
Labor, maintenance and sundries		0.0015
Fixed charges		0.0015
Total station costs		0.005
DISTRIBUTION COSTS		
Operation and maintenance		0.004
Fixed charges		0.004
Total distribution costs		0.007
ADMINISTRATION CHARGES		
Administration charges		0.0005
Total amount cost		0.0125
Profit required		0.004
Average sale price required per kw-hr. generated		0.0165
Estimated kw-hr. to be generated		60,000,000

The East 53rd Street station during these two months has been operating at less than one-fifth of its total capacity. The figures representing unit costs for the various items of labor, maintenance, fuel, etc., are, of course, considerably higher than can be obtained when the station is running up to its capacity, when it will be operating at a much higher efficiency in regard to coal consumption per kw-hr., and also the labor and other charges will be less per unit cost by reason of the larger output. During the month of August, the output of the Brooklyn and East 53rd Street stations amounted to 1,117,920 kw-hr., of which 936,467 kw-hr. were actually sold to customers, giving a loss in transmission of only 16½ per cent, the average sale price for the kw-hr., generated being \$0.0174 while the average sale price of what was actually sold was \$0.0207; the revenue for the month being \$19,405.38. The author states that an average load factor of 40 per cent on this station when the load is built up to its ultimate capacity seems to be assured, and in fact that a better load factor than this will actually be obtained. Prices charged for current for power purposes ranging from \$0.3 down to a minimum of \$0.01 become particularly attractive to factories, who are able to supply those conditions necessary for a good load factor, as is attested by the load factor which has already been secured on this station. A typical

FIG. 3 SWITCHBOARD AND 11,000-VOLT COMPARTMENT FOR SUPPLYING BUSINESS DISTRICT

load curve is shown in Fig. 4. In this curve the peak load is shown to be only 2700 kw., but with a load factor of 80 per cent based on the peak load, there is a total output on the generating station of 51,925 kw-hr. If these conditions can be maintained, or even approximated, when the load on the station has been built up to its ultimate capacity, the load factor will be considerably greater than 40 per cent.

EQUIPMENT OF STATION

The new plant has a maximum capacity of 25,000

kw. The special features in connection with the design of this station which are different from standard practice, are as follows: The use of motor-driven auxiliaries exclusively throughout the plant; the use of large boiler units with high steam pressure; the use of economizers of much greater capacity than ordinarily installed; a new arrangement of coal handling apparatus; the use of both forced and induced draft with practically atmospheric pressure in the combustion chamber; the automatic control of furnace con-

FIG. 4 TYPICAL LOAD CURVE, EAST 53RD STREET STATION

ditions; the simplicity of the piping layout, due to motor-driven auxiliaries; and the use of an auxiliary steam turbine for driving the auxiliary motors. This turbine is supplied with a jet condenser, whose cooling water is the boiled feedwater before going to the economizers.

The large boiler units are quite similar to those in the Debray Station of the Detroit Edison Company, which have been described in great detail by D. S. Jacobus, in the Transactions of this Society.¹ The dimensions are identical with those of the Detroit boilers, except the length of the drums. These boilers are installed with 10,000 sq. ft. of heating surface each, and are designed to carry 275-lb. working pressure with a superheat ranging from 125 to 150 deg. Fahr. They are equipped with Taylor underfed stokers, and are intended to be capable of operating up to 300 per cent of rating.

The operation of the boilers at a high percentage of rating means a higher temperature of flue gases. This, with the low temperature of feedwater, gives a temperature head between the flue gases and feedwater which will be practically double that ordinarily obtained in economizer practice. This alone would be sufficient to warrant the installation of a larger amount of economizer heating surface. Another factor, however, is the low interest rate of 4½ per cent on the investment to be balanced against the saving produced in the economizers. These were installed by the Green

¹ Trans. A. S. M. E., vol. 33, p. 565.

Fuel Economizer Company and have a heating surface of 27,000 sq. ft.

The use of both forced and induced draught contributes greatly to the flexibility of the installation, and makes it possible to carry practically a balanced pressure in the combustion chamber, thus avoiding one of the greatest sources of loss in boiler practice, namely, the leakage of air through the boiler settings.

The turbine equipment consists of three units of Allis-Chambers-Parsons type, rated at 5000 kw. each, 1800 r.p.m., 11,000 volts, A.C., steam to be supplied at 225 lb. per sq. in. gage pressure, and 125 deg. Fahr. superheat. The equipment of surface condensers was furnished by the C. H. Wheeler Company of Philadelphia. The power for the motor-driven auxiliaries is taken from a 1000 kw. turbine formerly in operation at the Brooklyn station, and will be operated in connection with a LeBlanc condenser, the cooling water for which will be drawn from a cistern used for the storage of the boiler feed water and which takes also the condensate from the three main turbines. The water in the cistern passes through the jet condenser several times before it goes as feedwater to the boilers and the connections are so arranged that the coldest water is supplied to the condenser and the hottest to the boiler feed system. The auxiliary motors in the station are connected through a double bus system so that each can be operated by current either from the auxiliary turbine or the main turbine. In this way the load on the auxiliary turbine can be adjusted so that the temperature of the feed water will be that best suited for delivery to the economizers.

Perhaps the most important innovation in connection with the operation of this station is not in the station itself. In central station practice in large cities it seems to have become a fixed rule to supply the congested districts with direct current through 220-volt 3-wire Edison systems, resulting in an enormous investment in copper, a much greater loss in transmission at the low voltages and also the loss of from 15 per cent to 20 per cent in transformation from alternating to direct current in the substations; and with the additional necessity of a greater number of substations than would be required for alternating current distribution.

It is a fact that nearly all lighting and power requirements can be met in the congested districts with alternating current as well as with direct current. There are, however, a few cases where the requirements can be met better with direct current but these constitute a very small percentage of the total. In power work there are places where finer gradations of speed control than can be secured with alternating current are desirable, and in lighting work there are places where storage batteries are necessary to provide an absolute security against interruption of service. But in such cases it would be much more econom-

ical to take care of the requirements on the premises of the customer and install there the necessary converters, accumulators, etc. The cost of this would be represented by thousands, whereas the investment necessary for the transmission of low voltage direct current from substations runs into millions of dollars.

In Fig. 3 is shown the arrangement of the 11,000-volt compartments and switchboard of the East 11th Street Station, which supplies the "down town," or the business district of Cleveland. The simplicity of the station and the absence of rotary converters is particularly notable when compared with the prevailing practice of supplying the congested districts of large cities from numerous substations in which are installed large numbers of rotary converters for changing alternating into direct current.

DISCUSSION

ROBERT L. BRUNET, in a contributed discussion, expressed approval of the method of operating the auxiliaries in the Cleveland plant. The objection to motor-driven units has been uncertainty of operation, which is removed by the single steam-driven unit which in this plant supplies power to the auxiliaries. He approved, also, of the use of both forced and induced draught in order to maintain a balanced pressure in the furnace.

As the author stated, the most important change in connection with the operation of the station is the use of alternating current for the congested business districts, instead of the Edison three-wire system. He knew personally of engineers of large central stations who find that there are practically no customers who cannot be properly and adequately served with A.C. as well as with D.C. current; and where the latter is absolutely essential, the transformation from A.C. to D.C. can be made on the customer's premises more economically than otherwise. There are important arguments against the use of D.C. current if high-voltage A.C. current can be supplied instead.

With low rates for current, both for lighting and power, it seems only fair to state that the load factor of 40 per cent will possibly be realized, based on a peak of 18,000 kw.; but when the peak is reached, the generating equipment will undoubtedly have to be increased in order to insure reliability and continuity of service. The load factor itself is dependent upon the diversity factor, i.e. the ratio of the sum of the separate maxima to the total co-incident maxima. In some stations where the load factor is in the neighborhood of from thirty to forty per cent, the diversity factor will be from 2 to 3 per cent—dependent primarily upon the means employed by the central station to obtain additional load.

The ratio of current sold for power to total power generated in modern stations varies from 50 per cent to seventy-five per cent and without this power business the rates for lighting would be decidedly increased to the small consumer. Engineers should not forget that a diversity factor in a station is the basis of profit and should receive the utmost consideration.

In making a study of the income of various central stations the writer has found that the income per dollar of investment varies in most private plants from 20 to 25 per

cent. Mr. Ballard has estimated an income of 33 per cent per dollar of investment. This seemed high to the writer, who thought it would be somewhat reduced by the fact that when the maximum of 18,000 kw. was reached the distribution system would be so extended that the actual investment would be greater than the figure used at this time.

The writer had prepared charts (not given herewith) showing the disposition of each dollar of income for a large private station and the estimated disposition of each dollar of income for the Cleveland municipal station. The private station has a capacity of approximately 350,000 h.p., with a total output of 840,000,000 kw-hr. per annum. The Cleveland plant has an estimated output of 60,000,000 kw-hr. per annum. In order to afford a close comparison the figures are tabulated below:

	Private Central Station, per cent.	Cleveland Municipal Station, per cent.
Labor.....	17	
Materials, etc.....	23	
Surplus.....	7	
	47	36.40
Dividends.....	15	24.20
Interest.....	9	13.63
Depreciation.....	11	9.10
Taxes and Municipal Compensation.....	7	4.55
Fuel.....	11	12.12
	100	100.00

J. R. CRAVATH, in a written discussion, called attention to one of the features brought out by this paper regarding the low cost of modern steam turbine plants as compared with turbine or engine plants of like capacity a few years ago. A cost of \$100 to \$150 per kilowatt of maximum capacity was common in large city stations until very recently. The decreasing cost of steam turbine units per kilowatt and the increasing steam output to which boilers of a given capacity are being forced in common practice, together with the small ground space taken up by large turbine units per kilowatt, have combined to lower power station costs. A short time ago costs of \$70 per kw. of station capacity were common for large steam turbine stations. In the present station, according to Mr. Ballard's figures, the cost of the station is about \$1,000,000, which for a maximum capacity of 25,000 kw. corresponds to \$40 per kw. On the basis of an 18,000 kw. peak load the cost is \$56 per kw.

Figures given as to investment and operating costs correspond with estimates made by the writer on a station of similar capacity intended to operate under conditions of rather high load factor. The thermal efficiency which is assumed by Mr. Ballard is about 11 per cent. This corresponds to modern good practice in actual working conditions with the station fairly loaded. This efficiency in the best and largest modern turbine stations ranges from 10 to 13 per cent. The unusual method used in the supplying of good condensing water is in part responsible for the low cost of the plant per kilowatt.

Whether the estimated maximum load of 18,000 kw. can be brought to the station under conditions existing in Cleveland with a distribution system cost sufficiently low to bring the total investment to only \$3,000,000 remains to be demon-

strated. The cost of a central distribution system depends upon the character and distribution of the load. If the station can be fully loaded with a distribution system covering a small area and serving mainly large power consumers, the cost may be under that given. If the distribution system is to cover a large city where the load density is necessarily low because of dividing the business with a competing central station, existing experience indicates that it is very doubtful whether the station can be loaded to 18,000 kw. with a total investment of \$3,000,000. The value of the power station being \$1,000,000 leaves \$2,000,000 for distribution system. With 18,000 kw. maximum load this corresponds to a cost of \$111 per kw. for distribution system. On a similar basis the cost of the entire plant would be \$167 per kw. of maximum load. It is probably not correct to take the cost of the Brooklyn system as a criterion of the cost of the 53rd Street plant with the distribution system when completed, but it is interesting to note that the Brooklyn system complete on a 1500 kw. capacity costs \$365 per kw. of station capacity. If the station is not fully loaded the cost per kw. of maximum load would be higher than this. If we assume that the Brooklyn station alone cost \$100 per kw. we would have \$265 per kw. maximum load for distribution system investment. Distribution costs, in general, run from \$100 to \$300 per kw. As before explained, their costs will depend very much on the load and the size of the consumers. A large number of small consumers greatly increases the investment per kilowatt in distribution systems.

As Mr. Ballard points out, the economy of production is much dependent upon the attainment of a high load factor. A number of years ago, load factors of 20 to 25 per cent (annual) were common. This has gradually been brought up by the acquisition of additional power loads and in some cases by taking on street railway loads. A load factor of 35 per cent (annual) is high for a station supplying electric light and power alone and stations obtaining 40 per cent have done so usually at the expense of many years of strenuous work. It is possible that by cultivating the large power business and ignoring the low load factor lighting business a 40 per cent load factor might be maintained from the start in an enterprise like that at Cleveland. It must not be thought, however, that such a load factor represents an easy attainment. The natural tendency of such a rate would be to load up the plant with low load factor business unless great care were exercised to prevent it. We thus see the importance of the fundamental principle that the rates charged must bear some proportion to the actual cost of serving these classes of consumers.

In order to put this undertaking on a fair basis for comparison with a private corporation, 8 per cent is added for profit. In allowing 8 per cent profit in addition to 4.5 per cent interest, Mr. Ballard has apparently inadvertently allowed considerable more annual return on the investment than would be necessary to clear him of a possible charge of unfairness to private corporations. Where commissions have passed on the question of reasonable return upon the investment in a plant of this character, the total annual returns, including both interest and profit, have been in the neighborhood of 8 per cent rather than 8 per cent in addition to interest. Mr. Ballard's fixed charges therefore should be reduced 4.5 per cent.

Fixed charges, depreciation and interest on the Brooklyn

plant with an investment of \$548,182 is given as \$19,079. This is only 3.6 per cent on the investment and appears to be an error. From the information given in the discussion, the depreciation on the Brooklyn plant would be considerably higher than for the 53rd Street plant inasmuch as a part of the Brooklyn plant investment would be written off as it is replaced by the 53rd Street station.

Depreciation on the complete plant is assumed at 3 per cent, calling for an average life of plant of 22 years. It is doubtful whether this is a sufficient allowance for depreciation even though it may be in accord with the customs of some private corporations. In the Madison Gas and Electric Co. case before the Wisconsin Railroad & Public Service Commission in 1910, the commission decided that the average life of the electric plant was about 17 years.

One element of first cost which can only be determined after the undertaking has reached the state of development anticipated in the preliminary estimates is that classified by the Wisconsin Commission as going value. Under this head is included whatever loss in operation is incurred in the early years of operation before the load has been built up to a point to yield a proper interest and profit on the investment. This amount must needs be added to the tangible physical investment to determine the total money put into the property.

WALTER C. ALLEN wrote that the paper omits a description of one of the features most interesting to electrical men, viz.: the distribution system. Apparently the new 53rd Street station is delivering its energy to the existing distribution system through the East 11th Street sub-station, without the use of rotary converters.

The loss in distribution from the Brooklyn station for the year 1913 as given is 27.4 per cent, while the loss for the first eight months of the present year, with the 53rd Street station operating with it during the last six weeks of that period, is 20.2 per cent. The loss during the month of August with both stations operating, is given as 16.25 per cent. In the absence of any further information regarding improvements in the distribution system, the reader must assume that this increased efficiency is brought about by the use of alternating current in the low tension system, instead of direct current through rotary converters.

It will be interesting to see what further efficiencies are obtained from the new distribution system, for which it appears \$1,500,000 is available.

ALEX. DOW said that he had followed the construction of the Cleveland plant with a great deal of interest. It is in a neighboring town, the consulting engineer is an old friend, the plant is a good one and a credit to the author. There is, however, much in the paper that is speculative. He hoped that at a later time when the proof of the performance of the plant was completed, the results, whatever they might be, would again be placed before the Society. At present, there is lacking a distributing system for the plant, there is lacking a load, and accounts kept in a manner which would be acceptable to a Public Service Commission. When these are realized we shall know the answer to the question of what the plant is accomplishing.

He further called attention to the author's statement of engineering matters, with no implication of lack of truth,

but because of slackness of expression which could not be overlooked when made by an engineer before an audience of engineers. An examination of the figures given shows the continuous duty of the station to be 18,000 kw. with good luck. He questioned the claims made for new and radical features. The record plant with which every engineer is familiar is at Dunstons, with the auxiliaries motor-driven throughout. The boilers of the Cleveland plant are rather less than half the size of those of the same type at Debray which have been in service five years and there is nothing radical in the increase of steam pressure from 225 to 275 lb. The balanced draft he remembered to have seen in use in torpedo boat practice when he was a "cub" on the Clyde.

Another inaccuracy is in reference to the figures upon the kilowatt hours generated. A note should be inserted that something like 10 to 15 per cent of this power is used in the station itself.

EDWARD W. BEMIS¹ in a written communication stated that he believed no candid student of the subject could doubt that Cleveland by its municipal control in various matters is securing better results than state regulation would secure. In the case of the Cleveland street railways certainly and until now, at least, in the case of the private electric light plant there, it has not deprived the private company of a fair return on its actual investment in the property, using investment to cover moneys furnished by the stock and bond holders in addition to good dividends from the start.

At the November Conference of Mayors in Philadelphia, Mayor Hocken of Toronto declared similar results were being secured by similar methods there. If these experiments continue to succeed, it is evident that state regulation will have to cease allowing companies returns on unearned increments, donation and surplus earnings invested in their properties, or existing laws in the various states will be changed where necessary to permit direct municipal competition under proper safeguards of publicity and uniform accounting, referendum on bond issues, etc.

It will be recalled that this method of potential municipal competition was endorsed by the National Civic Federation Commission on municipal versus private management, in 1907, as the most effective method of control.

When the efficiency of public operation approaches that of private operation, the handicaps upon the latter, through its demand for returns which public operation never makes, such as going value, and the increased cost of replacement as compared with actual cost, etc., to say nothing of differences in the demanded rate of return, will prove serious. Whether that time has yet arrived, and how far private companies will awake to the situation, as they have been doing in England, will vary with every community and with changing conditions.

R. P. BOLTON, in a written discussion, said the first thing to be considered is the foundation upon which the economic features of the plant are based. He called attention to the author's statement that the South Brooklyn Station had "made the remarkable record of having acquired more than one-half of its total value in eight years from the earnings of the plant itself" and said that so far as the details

¹ 14500 Beacon St., Chicago, Ill

of these earnings are made available in the paper itself he felt that the diversion of such earnings was not warranted.

According to the figures of the author, the capital investment to the end of 1913 was \$320,796 and the amount added from the earnings prior to providing for necessary fixed charges was \$306,533, or a total of \$627,329.

This account is credited with \$109,147, which could or would have been paid to a local company for street lighting. This amount, however, almost exactly offsets a book charge for depreciation of \$113,244 so that any money for the latter necessary purpose has been burnt up and the value exists only as a book debit. The character of part of the earnings may be seen by comparing the figures of operating income in Table 3 with the item for 1913 in Table 2. The net earnings for 1913 were \$68,979; earnings put back in the plant, \$66,622; which leaves only \$2,357 to pay fixed charges of \$19,079.

The income of the South Brooklyn plant had been secured in 1913 by an average sale price of 3.28 cents per kw-hr., while for the first eight months' operations of the old and new stations the rate had decreased to 2.44 cents per kw-hr. The direct loss on the South Brooklyn system is therefore \$4,100 of a cent, and allowing for the economy in production cost due to the new plant's operation, the net loss is,..... \$31,100

Turning to the figures of operation of the new plant, we find:

The earnings for August were, at the average rate of 2.07.....	\$19,405
Average of 8 months monthly operating cost.....	12,130
Leaving for administration and fixed charges....	7,275
The fixed charges are stated to be per month.....	22,500
Resulting in a deficiency, for the month, of.....	15,225

It is upon this somewhat rickety foundation that the basis for estimating results in the 53rd Street Station has been predicted.

The writer contends further that the successful financial operation of the plant is dubious, not only by reference to the data upon the operation of the Brooklyn station, but also in consideration of the character of the service to be rendered and the rates to be charged.

The service is to be for alternating current only, which for much of the business of Cleveland will be unattractive and much direct-current machinery will have to be altered or discarded for its adoption.

Details of the rates are not given in the paper, but from those which he has found in the records of the municipal council he believes they are such as to offer but little inducement to those customers whose usage is the most desirable in producing a high load factor. A diagram plotted by the writer indicates that the inducements of the rates are toward high connected capacity which is a source of production of high peak and low load factor.

He asked: Are there any data in the paper which justify the expectation that the small consumer can be served at the rate of 3 cents without loss, which must be borne by other consumers or by a deficit in operation? The total costs of the 936,000 kw-hr. sold in August were, without administration, \$34,630, or, per kw-hr. 3 7/10 cents. The figures made public by the Detroit Edison Co. show their cost of service connection, upkeep, meter installation, lamps, accounting and bill to be per customer \$8.41 per annum.

This is over and above the cost of producing and delivering the energy used.

THE AUTHOR said that he had been told so often that they were radicals up at Cleveland that he was glad to learn that Mr. Dow did not consider anything in this station to be at all radical and that they had built a plant so nearly like the Delray station. There was no reason why the latter should not sell their current at the same price as the Cleveland station and he hoped to see them do it.

With regard to the capacity of the station, there is some degree of uncertainty in the method of rating power station machinery and power stations. He understood that stations at the present time are generally rated upon their maximum continuous capacity. Tests showed that these turbines are capable of 7500 kw. continuous capacity; three of them would give 22,500 kw. and the auxiliary machine would add 1500, making 24,000 kw. maximum continuous capacity. That was the basis on which he had made all his statements in regard to capacity.

In Mr. Cravath's discussion, the figure of \$365 is the cost per kw. of the entire Brooklyn plant, including the distributing system. As shown by the appraisal, he thought the value of the distribution system was about \$200 per kw. and of the station itself from \$160 to \$175.

As to whether it will be possible to get a 40 per cent load factor, the system is now running with between 60 per cent and 80 per cent load factor and while he realized that as the load was built up they would secure a much poorer load factor, he believed it would not go below 40.

The question has been raised in regard to cost per kilowatt-hour. It is true that this differs greatly for different classes of customers and the Cleveland plant is radical in that respect in that it is selling current to some customers at a loss.

The waterworks department at Cleveland is selling water at a uniform rate to everybody, the smallest household user as well as the factory. That is probably going to the other extreme, but they are subject to no competition. Of course, this cannot be done with electric current. Outside of the question of competition, if there were only one station and every customer had to take that current or none at all a single rate could not be maintained. Current could not be sold to the small residence customers at as low a rate as it would be necessary to sell to power customers and the business could not be obtained, on the other hand, if power customers were charged at a higher rate than residence customers.

Mr. Bolton raised a question as to the \$66,000 reported turned back into the plant from earnings, whereas \$49,000 is shown in the report as profit. This, however, is correct although it appears on the books in the way of depreciation. Many companies are mistaken at the present time in setting up 10 or 15 per cent for depreciation year after year. The point will soon be reached where the book value of the plant is very much less than the actual value. He instanced the case of a large company, the plants of which he had appraised, and found the value to be thousands of dollars more than their books showed, simply because they had been writing off too much depreciation. This method of setting up depreciation was followed with the Brooklyn plant and is where the difference comes in between the \$49,000 and the \$66,000.

FOREIGN REVIEW AND REVIEW OF PROCEEDINGS OF ENGINEERING SOCIETIES

ENGINEERING SURVEY

The war in Europe has materially affected the files of foreign periodicals. While most of the papers come in with fair regularity, both their size and intrinsic value of contents have suffered to a noticeable degree. The Belgian papers have been discontinued entirely, the French appear in a reduced size, while most of the German papers have adopted the system of publishing double numbers, sometimes with less reading matter than the former single number. When, however, one sees the long lists of the members of various engineering societies fallen on the fields of battle, one has no difficulty in understanding the decrease in the output of papers.

THIS MONTH'S ARTICLES

The investigation of a gas-driven compressor air plant at the Mine Consolidation is of interest because it is the first large air compressor plant so driven in Germany, and while there is nothing startling in the results obtained, the overall efficiency of the installation is fairly high.

Attention is called to the article on Pelton turbines, especially because it is believed to be the first authentic information on the Fully plant, using the highest head of water, in a single jet, in the world. In the same abstract, data are given on the Dufour water wheel governor.

In connection with an article on a 1000 h.p. Diesel engine is reported a method of governing the pressure of the fuel injection air, which will facilitate the use of Diesel engines on constantly varying loads, such as are met with in central stations supplying energy to tramway systems.

The article on elastic hysteresis does not present anything essentially new, but it is reported here because it refers to a matter to which hardly enough attention has been given in American engineering papers.

The section on steam engineering contains several interesting articles. Tests are reported on the use of eddy rings, a device somewhat similar in shape, though different in action from what is known in this country as retarders; data on accident in gas fired boilers are reported, and a new type of traveling grate is illustrated and described. Further, a new type of liquid fuel burner, of the adjustable kind, is described, it is also stated that this type of burner has been a success in the Austrian navy.

In the last section the Plumboxan process of producing oxygen and nitrogen is described.

In the section Engineering Societies, the following papers are reported or abstracted:

E. S. Christian, in a paper before the American Wood Preservers' Association, gives data on the preservation of a pier at Newport News, Va., against the action of marine borers by means of dead oil, the pier having withstood the attacks of the borers now for 32 years.

J. H. Waterman presents data on ties treated by various processes such as the Full Cell creosote, zinc chloride, Wellhouse and Card processes. Also a specification for a coal tar creosote solution is reported.

Milton L. Sims, in a paper before the Central Railway Club discusses the matter of painting of steel cars and

locomotive equipment and many other things, giving schedules of time for various painting jobs.

In a paper before the Corps of Engineers of the United States Navy, Captain W. A. Mitchell presents important experimental data on the percolation and upward pressure of water necessary in order to design dams properly.

Tests on various reinforced concrete structures in England are reported in a paper by J. B. Hall before the Institution of Civil Engineers. Before the same body, S. H. Ellis presented a paper on the corrosion of steel wharfs at Hongkong, China, containing data which may be of interest to any engineer working in the tropics.

Particular attention is called to the paper by Thomas Bryson before the Institution of Mining Engineers, on the testing of fans with special reference to the measurement of pressure, and containing other things and valuable data on the efficiency of various forms of water gages.

Genjiro Hamabe, of the College of Engineering of the Kyoto Imperial University, discusses the disturbing actions of a shaft governor. While the paper is too mathematical to be fully abstracted in some of its parts, an attempt has been made to present the main line of reasoning of the author in a moderately readable form.

The two papers by Professor B. Hopkinson, on the charging of 2-cycle internal combustion engines and H. F. Fullagar on a new type of internal combustion engine before the Northeast Coast Institution of Engineers and Shipbuilders refer to tests on the same engine, but Professor Hopkinson's paper takes up the entire subject of charging, which he discusses in a novel and highly interesting manner.

The analysis of coal with phenol as a solvent by S. W. Parr and H. F. Hadley gives not only a method of coal analysis but presents data of material interest to all those who have to do with the utilization of coal in a boiler, furnace, coke oven or gas producing plant.

FOREIGN REVIEW

Air Machinery

INVESTIGATION OF A GAS DRIVEN AIR COMPRESSOR PLANT AT THE MINE CONSOLIDATION.

The article describes a gas engine driven air compressor installation at the Consolidation mine in Germany and gives data of tests of this installation.

While gas engines have been used widely to drive electric generators, their use for air compressor operation in Germany appears to have been very small and only in installations of an experimental nature. The present installation, therefore, represents a very bold advance involving a compressor handling per hour 15,000 cbm. (say 530,000 cu. ft.) from atmospheric pressure to a pressure of 6 atmospheres gage. The gas engine is a four stroke cycle twin tandem engine working on coke-oven gas with a heating value of from 4,000 to 4,500 W.E. (448 to 504 B.t.u. per cu. ft.). The high pressure and low pressure cylinders of the air compressor are directly connected to each of the sides of the gas engine, each side of the engine being so designed that it can compress as a single stage compressor from 4800 to

7000 cbm. (169,500 to 247,200 cu. ft.) per hour to a pressure of 5 atmospheres, according to whether the high or low pressure cylinders are operated. The arrangement is such that even when the engine is being cleaned, or undergoing repairs, the compressor is still partly running.

When the engine is operated at its full capacity of 45,000 cbm. per hour it has a speed of 90 r.p.m. The compressor has Horbiger-Rögler plate valves conveniently located in

TABLE 1 TESTS OF A GAS ENGINE DRIVEN AIR COMPRESSOR EQUIPMENT

Duration of test, hr.	6

Average temperature of compressed air, deg. cent. Fahr	138 280

a valve chamber in such a way that they can be easily exchanged. In order to attain as low an air temperature as possible and, further, in order to comply with the police requirement that the temperature in a single stage compressor should not exceed 140 deg. cent. (284 deg. Fahr.), the walls of the compressor as well as the compressor piston are water-cooled. The intermediate cooler which permits the cooling down of the partly compressed air to the temperature of suction is placed in the floor in an accessible position. A tube filter of the Blass type is used for cleaning the air in suction.

The engine was subjected to an acceptance test in the period from September 29th to October 4th, 1914, and a further control test on October 13th. The work of the cylinders of the gas engine and compressor were determined by indicating the air pressure and temperature by properly calibrated manometers and thermometers, while the heat content of the gas was determined by analysis and by means of a Junker calorimeter.

In order to eliminate the influence of outside temperature and the action of sun rays on the gasometer, all the tests were carried out after the sun went down. Nevertheless it has been found in testing the air tightness of the gasometer that the pressure lever continued to sink after sundown and this led to the control test on October 13th. The data of the test are shown in Table 1. This test has shown that the plant as it stands did not satisfy entirely the very exacting requirements of the contract but that it was fairly efficient. During the entire test, the engine ran quietly without causing any trouble, and no disturbances of any kind in the operation of the plant were observed. (*Untersuchungen des Gas-Luftkompressors auf der Zeche*

Hydraulics

PELTON TURBINES AND THEIR GOVERNORS.

The article (continuation of the one abstracted in *The Journal*, January 1915, p. 14) describes Pelton turbine installations in Saasheim, Norway and Fully, Switzerland.

The installation in Norway was built for a fall of 253 m. (830 ft.) and an output of 16,400 h.p. at 250 r.p.m. It is a turbine with two wheels and two needle nozzles per wheel. The average diameter of the wheels is 2.4 m. (94.4 in.), the number of blades, 26, and the maximum diameter of the jet, 0.164 m. (6.4 in.). A figure shows the disposition of the nozzles, water admission to them and regulation and distribution of the blades in the wheel, the casings with the foundation frame and the arrangements for letting off water into the shaft. Fig. 1 A indicates the method of holding the blades.

The turbine is equipped with a combined needle displacement and jet deflection in accordance with the Leon Dufour patents. Fig. B, p. 45 indicates the method of operation of this system of control in a manner which permits its comparison with the method of control indicated in Fig. C, p. 45, *The Journal*, January 1915. The rocker *abc*, with the rigidly located center of rotation at *b*, is, at *a*, connected with the pistons of the servomotors. At *c* is suspended the first main element of mechanism, viz. a bar *cd*, bent in accordance with the predetermined curve, this bar being connected with the needle rod by means of the deflector *de*. The bar is further connected with the jet deflector by means of a rod *ik*. The servomotor consists of two parts, viz. of the main servomotor, equipped with a differential piston and a displaceable pressure servomotor located coaxially with the main. The casing of the latter is inserted into the smaller working space of the main servomotor so that an axial displacement of this casing is possible. The piston of the pressure servomotor is connected rigidly and invariably with the piston of the main servomotor, while this casing is connected by means of the guide *fg* with the jet deflector. With the rigid bearing of the rocker *abc* is connected a roller which limits the deflection of the bar to the right.

From the above description and Fig. B (which, however, represents the construction only diagrammatically), it is clear that as long as the permanent contact is maintained between the bar and the roller, each position of the piston, 0, 1, 2, 3, 4, of the main servomotor corresponds to a definite position indicated by similar numerals of the deflector edge *e*.

The Pelton turbine of the Fully plant is of the greatest interest because in the plant, a total flow of 1650 m. (5412 ft.) between the Lake Fully and the valley of the Rhone is utilized in one stage, which naturally leads to the necessity of solving some quite interesting problems in the selection of materials and design of piping for stresses produced by such a head. No complete data have been published as to the method of conveying the water and of the piping. The author is only enabled to state that the total piping is 4625 m. (15,172 ft.) long; that its upper part, 2300 m. (7545 ft.) long uses a diameter of 0.6 m. (23.6 in.) while in the remaining lower part, the diameter is 1.5 m. (19.6 in.);

that the thickness of the walls of the pipe varies from 6 mm. (0.23 in.) to 43 mm. (1.69 in.). Up to a thickness of 34 mm. (1.33 in.), the steel piping has been produced with longitudinal and cross seams welded by a special process. The piping of a thickness of 34 to 43 mm. consists of pieces drawn from single block without longitudinal seams and combined into pipe sections by autogenous welding, the connection between such sections being made by welding on connections with loose flanges and rubber ring packing. The entire main piping is located underground and is covered with earth at least 1 m. deep.

The prime movers consist of five units of 3000 h.p., each driving poly-phase generators operating at 10,000 volts and 50 cycles. The turbine installation as shown in the original article has a runner of 3.55 m. (11.65 ft.) theoretical diameter with 54 pressed steel blades. The method of fixing and holding the blades is shown in the lower left hand section of Fig. D. The 54 blades are distributed into nine groups of six blades each, such groups being separated by trapezoidal prisms.

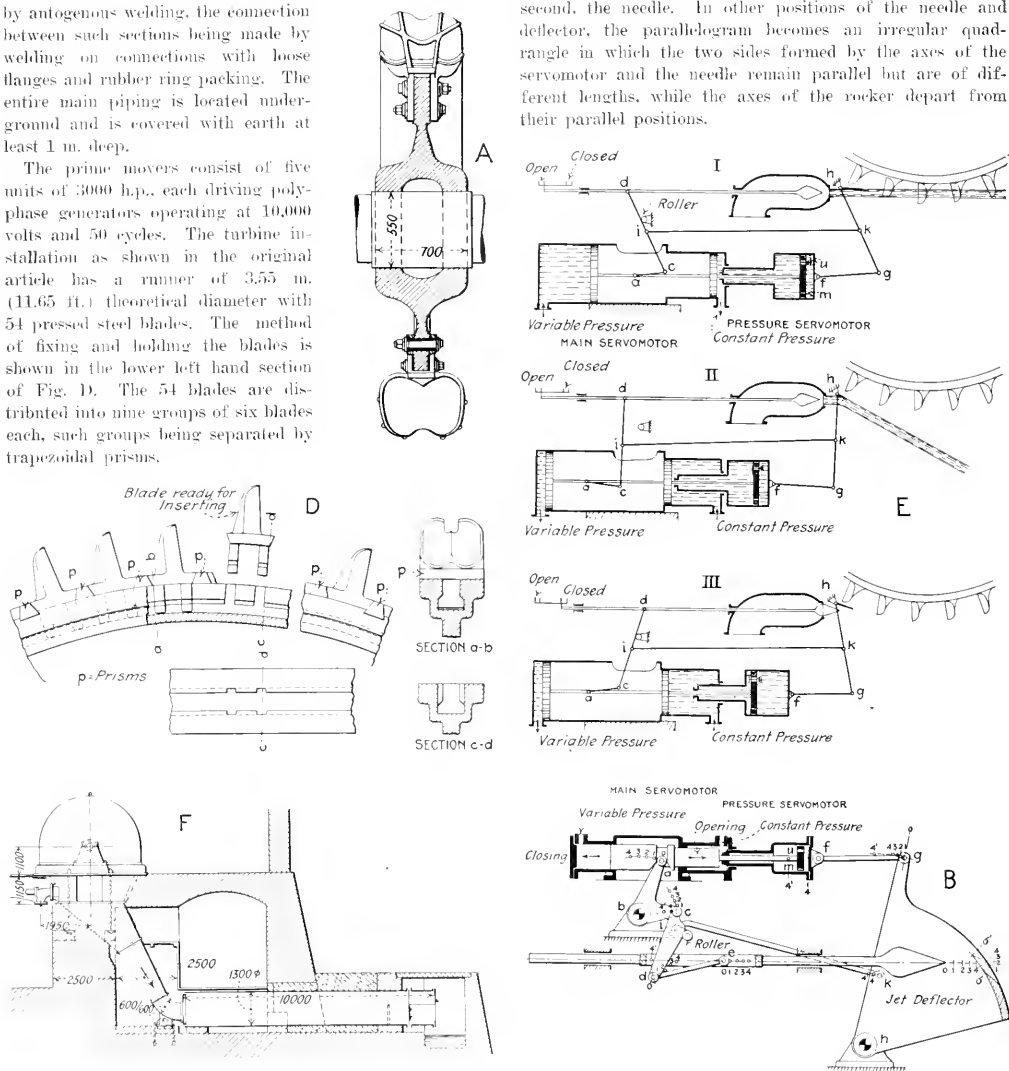

FIG. 1 PELTON TURBINES, THEIR BLADES AND GOVERNORS

This turbine is equipped with a combined Leon Dufour regulation similar to that described above but its actual construction, as indicated in Fig. E, is different from that used in the preceding case. In order to make the comparison between Fig. E and Fig. B easier, similar parts are

indicated by similar letters. Fig. E shows also the fundamental geometric conception of the device characterized by the parallelogram consisting on one hand of the rocker *dc*, between the servomotor and needle rod, and the rocker *hg*, parallel to *dc* when the nozzle is fully open and connecting the pressure servomotor and jet deflector; and on the other hand, first, by the parallel axes of the servomotor and, second, the needle. In other positions of the needle and deflector, the parallelogram becomes an irregular quadrangle in which the two sides formed by the axes of the servomotor and the needle remain parallel but are of different lengths, while the axes of the rocker depart from their parallel positions.

With the fall of 1650 m. available, the velocity with which the water leaves the nozzle is somewhere around 180 m. (590 ft.) per second and even after it leaves the wheel, it still has a velocity of from 35 to 40 m. (105 to 131 ft.) per second. It is of particular importance therefore that the

water should not strike the walls of the outflow shaft, and an arrangement resorted to is shown in Fig. F. It consists of a special cast iron shield on the upper end of the shaft and close to it, a sheet metal passage, located in an inclined position with a contraction toward the lower part, into which the various grids are built and which opens through a quarter bend into a horizontally located sheet metal cylinder 10 m. (32 ft.) long and 1.3 m. (51 in.) in diameter. (*Die Wasserturbinen und deren Regulatoren an der Schweiz. Landesausstellung Bern, 1914*, Professor Franz Präšil, *Schweizerische Bauzeitung*, vol. 64, no. 24, p. 257, December 12, 1914, serial article, not finished, d).

Internal-Combustion Engines

1000 H.P. DIESEL ENGINE

The article describes in addition to heat and refrigeration

thing, more or less, of the admission of air into the first stage of the fuel injection compressor. The variable initial pressure causes a fluctuation of the final pressure which later attains a maximum for large charges and is reduced by about one-third for small charges. Further, by means of a servomotor and through a variable pressure at one of the stages of the compressor which delivers the air of injection, it is quite possible to regulate the motion and the time of opening of each fuel valve. As a result, the air of fuel injection can penetrate into the working cylinder only in quantities fully subject to regulation, so as not to be in the way of the propagation of the flame at the instant of the combustion of the injected fuel.

The air of injection should always have a pressure several atmospheres above that which exists in the cylinder at the end of compression. If this air has been sufficiently cooled

FIG. 2 A 1000 H.P. DIESEL ENGINE

engines at the National Swiss Exhibition of 1914 at Berne, a 1000 h.p. Diesel engine of a rather interesting type. (Fig. 2)

The engine is of the four-stroke cycle type with four fixed cylinders. In addition to a judicious disposition of the cylinders held by vertical steel tie-rods, the engine has also an automatic regulation of the pressure of the fuel injection air. To make the combustion more perfect, this pressure has to be regulated in accordance with the charge. In this case, the speed governor of the engine provides for this kind of regulation. To each load there corresponds a certain predetermined position of the governor sleeve and this, by means of a cylindrical valve, permits the throt-

after each compression, it will have essentially the temperature of the surrounding medium, and the latter will, to a sufficient extent, go down during the expansion, to cause a considerable cooling and to provoke not only a defective combustion, but if the air of injection enters in too large quantities, a failure of ignition, which in its turn can cause grave disturbances in the regulation and make working in parallel impossible. The Salzer regulation entirely eliminates this cause of trouble and permits the building of motors for constantly varying loads, such, for example, as in central stations supplying energy to tramway systems, etc. *Les machines thermiques et frigorifiques à l'Exposition nationale suisse de 1911, à Berne*, Professor J. Cochand, *Bulletin technique de la Suisse Romande*, vol. 40, no. 23, p. 261, December 10, 1914, serial article, not finished, d).

Mechanics

RECENT EXPERIMENTS ON ELASTIC HYSTERESIS.

Discussion of phenomena of elastic hysteresis in solid bodies.

When a solid body is subjected to an elastic deformation within certain limits, the deformation is exactly proportional

to the force applied. This region of deformation is known by the name of Hooke's, and its limit is called the limit of elasticity. It has hitherto been accepted in the theory of strength of materials that an elastic deformation within the Hooke region is reversible, even though there are certain phenomena which contradict this view, such for example, as the fatigue of materials. Lately, however, by the application of especially delicate methods of observation, the processes occurring in elastic deformation within the limits of elasticity have been better investigated experimentally, and it has been found that the proportionality between deformation and force applied, as expressed by the Hooke law, does

FIG. 3. HYSTERESIS LOOP OF ELASTIC DEFORMATION.

not hold good exactly, and one cannot strictly speak of the reversibility of this process. On account of the similarity of the processes (see the tension-elongation diagram in Fig. 3) with magnetic hysteresis, this phenomenon was called elastic hysteresis. It may be explained by the assumption that the deformation lags behind the force so that if the point of reversal be suitably selected, a closed curve process can be produced.

In the above diagram OA is the virgin line of the material newly stressed in tension. ABC shows its contraction down to the state C and CDA the more recent expansion into the state A . The curve becomes a closed one when A and C are symmetrically located with respect to the zero point and in further cycles of the process practically the same path is repeated over and over again in the direction of the arrow. Further, since the energy of a unit of volume of a body elasti-

cally deformed is given by the expression $\int \sigma d\epsilon$ where σ is the stress, and ϵ the deformation, the area of the hysteresis loop in a circular process is numerically equal to the work lost per unit of volume, such work having been partly transformed into heat and partly used up on the displacement of the molecules, and has thus possibly led to the rise of fatigue in the material.

It may be added that this phenomenon occurs in as pure a manner as here indicated only when the stresses remain within the Hooke region and when so large a number of these cyclic processes have been gone through that the material has sufficiently adapted itself to the process. In addition to that, the hysteresis phenomena are always superimposed by the so-called elastic reaction which after each appli-

cation of strain permits the molecules to assume their initial position of rest only after the lapse of hours and sometimes days.

The author proceeds to the presentation of data on elastic hysteresis obtained by Professors Hopkinson, Trevor-Williams and F. E. Rowett in their tests in the Engineering Laboratory in Cambridge which were published in the Proceedings of the Royal Society of London, Ser. A, vol. 87, p. 502, and vol. 89, p. 528. (*Neuere Versuche über elastische Hysteresis*, Dr. R. Grammel. *Zeits. des Vereines deutscher Ingenieure*, vol. 58, no. 48, p. 1600, November 28, 1914. 3 pp., 3 figs. *te*).

Steam Engineering

BOILER ACCIDENT

The article describes an accident to a boiler fired with producer gas.

It is taken from a report of the Mountain Boiler Inspection Association of Barmen, Germany. The boiler was of the double flue type, fired with producer gas, with the steam collector in the upper flue, 100 sq. m. (1076 sq. ft.) of water heating surface and 6 atmospheres licensed pressure. Up to the time of the accident, the boiler had been in operation for nearly 7 years. The gas was developed in a coal gas producer located in the boiler house, while the combustion chamber was directly in front of the boiler. The first rings of both flues were covered with fire clay lining with an inner diameter of 580 m. (22.8 in.). According to the general regulations for licensing gas fired boilers, the ratio of grate area to water heating surface (such "water heated surface" being that which the heating gases play on, before they reach the heating surface in contact with the steam) was determined on the basis of an ideal grate area of 2.1 sq. m. and a ratio of grate area to heating surface as 1:47.5. The air was forced into the combustion chamber by a fan. When the plant was licensed in 1905, the minimum cross section of draft was used for the determination of the ideal grate area, as in the inspection regulations at that time, there was no precise indications as to the methods of calculating the grates.

In June 1913, the boiler was cleaned, but this cleaning had to be done with great speed as another boiler which was also fired by producer gas met with an accident in the meanwhile. After the boiler had been started again, it was fired at a high rate for 24 hours, but it was found impossible to obtain any noticeable pressure. At the same time, the evaporation appeared to have been quite strong as it was necessary to supply feed water all the time. When the fire was allowed to go out, it was found that the parts of the boiler shell and the steam collector shell in contact with steam must have been red hot. The shell girth seams had been drawn apart, so much that one could see through them into the inside of the boiler. The steam collector shell indicated strong outward bulging, while the front sheet of the collector was blown out into a hemisphere. The steam which was produced during the heating evidently escaped through the openings in the seams at a very low pressure into the upper flue and thence into the smoke stack.

Investigation has shown that the accident was due to the after-burning of gases in the upper flue which had not been burned entirely in the combustion chamber on account of lack of air. It is quite impossible that the temperature

of the hot gases, after complete combustion in the combustion chamber, should have been so great when coming in contact with the steam heating surface that it could have produced such effects as were found in the boiler. It is quite possible, however, that the after-burning was helped also by the air coming directly into the upper flue. This accident indicates that in boilers precautions should be taken to prevent the steam heating surfaces from being acted upon by the hot gases, as incomplete combustion of the gases in the combustion chamber is always possible. *Aus der Überwachungspraxis, Zeits. für Dampfkessel und Maschinenbetrieb*, vol. 37, no. 51, p. 544, December 18, 1914, 1 p., dp).

EDDY RINGS IN FIRETUBE BOILERS.

The article reports tests with eddy rings, a special device for increasing the efficiency of boiler fire tubes.

The action of eddy rings provides for deflecting that part of the gas stream flowing through the fire tubes of a boiler which is nearest to the walls of the tube and therefore coldest and in this way mixing it with the hotter part of the gas stream, thus securing a fuller exchange of heat between water and gas. The construction of the eddy rings is shown in Fig. 4A. From it, it is seen that the action of the eddy rings

superheaters, a part of the tube cross-section being occupied by the superheater coils. It is necessary, however, in such a case that the free section of the tube be large enough to provide for an unobstructed passage of the gases. It does not appear that these rings affect the draft in the smoke stack, but it is quite possible that after the installation of the superheater the draft in the smoke stack may be reduced to such an extent as to weaken materially the action of the eddy rings.

Practice has shown that the installation of the rings involves certain difficulties. In the first place, the diameter of the tubes is not the same throughout and even in the same tube small differences are noticed in the free cross-section. Further, the data as to the internal diameter of the tubes

FIG. 4 EDDY RINGS FOR MARINE BOILER TUBES

is essentially different from that of retarders, in which the gas stream is divided into two parts and is given a helical forward motion, without, however, enabling the inner hot gases to reach the walls of the tube.

The first tests with eddy rings of the Pielock system were made in 1910 and on the whole, have been successful. It is now stated that 50 ships have been equipped with the Pielock rings. The article gives detailed data of tests made with and without Pielock rings on various steamers, mainly barges and tugs. It may be of interest to state here that the first Pielock rings were installed on the condition that the coal saving should be guaranteed at not less than 10 per cent; that a fine of \$50 be paid by the company installing the rings for each 1 per cent of saving of coal less than 10 per cent and that should the saving in coal not reach 5 per cent, the company would take out the rings free of charge and defray the entire cost of the test. Under these rather severe conditions of contract, a saving of 15 per cent was effected.

As an example of the various tests reported in the article, we may select those made with three tug steamers, Moritz, Otto and Ernst (Table No. 2). The trips were all made against the tide, drawing one barge of approximately equal load in each case and using the same kind of coal in the boilers.

The author states that eddy rings can be used also in

are not always reliable and it has happened more than once that rings turned exactly to a supposed diameter of the tube, either did not go in at all or were so loose that they dropped into the firebox during the trip. This led to rejecting the direct insertion of the rings and adopting a different method. The rings are now turned somewhat smaller than the diameter of the tube, but each ring is held (Fig. A and B) by means of two flat iron bars, located along the axis of the tube in such a manner that the rings cannot then drop out. A series of rings therefore is put into each tube as a unit and can be quite easily withdrawn, for example if any repairs on the tubes have to be carried out.

This method of using withdrawable fire rings has proved to be very desirable in view of the ease of installation and for this very reason, such rings have a material advantage over the so-called retarders. Tests with these withdrawable rings have shown results practically similar to those with specially installed rigid rings. The author claims that eddy rings can be used to advantage also in feed water preheaters and air heaters of the Howden boiler installation. A figure in the text shows an air preheater for a modern boiler plant. In condensers, the rings can be applied only when the cooling water is pure, because otherwise, the deposits would rapidly reduce the free cross-section of the tube, but if the dimensions and arrangements of the rings have been properly selected, it is claimed that beneficial results can be obtained thereby. (*Betriebsergebnisse mit Wirbelringen in Feuerrohrschiffkesseln*, Forst, *Schiffbau*, vol. 16, no. 1, p. 72, November 25, 1914, 6 pp., 6 figs., d.).

PLACZEK TRAVELING GRATE.

Description of a traveling grate essentially consisting of chain elements and intervening grate bars.

The main purpose of the new construction was to avoid as far as possible the rapid wear of the grate elements and to provide for an easy exchangeability of parts. Two guiding chains provide supports for the grate bars while the links of the chain carry the grate bar supports on which lie the grate bars themselves either longitudinally to or across the motion of the grate in such a manner that they may be easily removed when desired. In this way, the chain itself lying outside of the path of the grate proper is not affected directly by the heat of the furnace and is rather subject to a cooling by the air of combustion, which results in its wear being considerably longer. Further the grate bar elements can be changed in any desired way and a grate surface can

FIG. 5 PLACZEK TRAVELING GRATE.

be obtained so as not to be fully continuous. As a result of that, it is more uniformly and efficiently cooled by the air of combustion. In changing to a different kind of fuel, the economic combustion of which requires a different type of profile of the grate bars it is not necessary to replace the entire grate. All that has to be done is to put in a set of new bars of the desired profile, as the old and used up bars are being taken out.

The traveling grate of this new construction in which the separate grate bars, together with their bearers, can be so easily exchangeable that it is not necessary to have the entire grate removed, has been patented in Germany by Placzek. It is shown in Fig. 5. The grate as shown is 2650 mm. (104 in.) long and 1700 mm. (66.9 in.) wide. Essentially it consists of the two chains running right and left on rollers at *c c'* which carry the grate bar bearers and through them the grate bars themselves. The guides *c* are located in passages *b* in the brick wall, while the chain itself, and by it the entire grate, is carried forward over the driving drum *a*. The rear guide is limited to the terminal section of the grate which is provided with a suitable curve. The drive of the grate by means of the driving drum is continuous and is

effected by a worm gear drive running in an oil filled gear case on ball bearings with staged discs and belt tighteners *d* in such a manner that the movement of the grate can be easily and quickly adjusted to three or more different speeds. The grate bar bearers located cross-wise are placed in the elements of the chain in such a manner that they can be easily withdrawn. The grate bars, selected so as to have the full path adapted to the kind of fuel used, have an essentially triangular cross section and should be placed on the bearers by one of the corners. In the upper part of the path of the grate they are, on account of their system of guiding, in such a position that they overlap one another and a practically closed surface is presented to the fuel. The part of the bar lying in front of the coal hopper end is just in this position, but when the rows of the grate bars are carried over the rear curved guide, the guides tilt around the bearers and then in the lower grate they hang downwards practically free so that they can be easily pulled out. (*Der Wanderrost System Placzek, Pradel. Zeits. für Dampfkessel*

FIG. 6 ADJUSTABLE BURNER FOR LIQUID FUEL

and *Maschinenbetrieb*, vol. 37, no. 49, p. 523, December 4, 1914. 3 pp., 3 figs. *d*).

ADJUSTABLE BURNER FOR LIQUID FUEL.

Description of an adjustable burner for liquid fuel, especially naphtha, of late widely used on Austrian ships.

The burner, as shown in figure A, permits very good regulation of fuel admission simultaneously with perfect atomization of the fuel which is made possible through the fact that the atomizing tip of the burner, provided with several nozzles, is equipped with a regulating device made in the shape of a rotary valve. According to the position given to it, this device either closes all the nozzles or permits the connection of a desired number of such nozzles with the fuel admission pipe.

The atomizing tip of the burner equipped with four atomizing nozzles is screwed into a casing of the burner. One of these nozzles is located in the center of the atomizing tip, while the others are disposed around it in a circle. The fuel passages leading to them open into a conical hollow opening in the atomizing tip in such a way that two of the fuel passage openings are located opposite one another at equal distance from the center of the working surface of that

hollow opening, while openings of the two other passages are disposed along circles of equal diameter and at distances of about 120 deg. from each other. (Compare Figure 6 A.)

On the atomizing tip is located a rotary valve which can be rotated by means of a spindle and hand-wheel and is pressed against the atomizing tip by a spring. In this rotary valve, there are three circular slots, two long ones extending over an angle of somewhat more than 90 deg., and a third slot, somewhat shorter. The radii of curvature of these slots correspond to the radii of the circles over which are located the openings of the fuel passages, so that in a proper position of the rotary valve, the shorter slot is located opposite the two inner passages, while the longer slots are opposite the outermost passage, the middle slot being placed over the middle position. In this case, the crude oil fuel passes through the admission pipe to the slot in the fuel passage of the atomizing tip standing in connection with the proper slots. As shown in Fig. B (4), the smallest slot of the tip is opposite the passage leading to the middle nozzle, while the other slots are still about 90 deg. away from the proper openings of the passage so that fuel is led in (5) only through the outer and middle nozzle which heat the upper part of the fire tubes particularly. With the further rotation through 90 deg. (6) the smallest slot covers the inner passage, while the rear end of the two upper slots are right opposite the corresponding passage openings, so that all the nozzles, with the exception of the central one, are in operation. Should the valve be turned through 90 deg. more (7) then all the slots come out of correspondence with the fuel passage openings and the fire in all the nozzles is put out. It is claimed that this type of burner in the Austrian marine has proved to be efficient. (*Einstellbarer Brenner für flüssige Brennstoffe, insbes. für Naphta, Der praktische Maschinen-Konstrukteur*, vol. 47, no. 51, p. 332, December 24, 1914, 2 pp., 2 figs., d.)

Miscellanea

THE PLUMBIXAN PROCESS FOR PRODUCING OXYGEN AND NITROGEN FROM ATMOSPHERIC AIR

The article describes the so-called Plumbixan process for the recovery of oxygen and nitrogen out of atmospheric air and the apparatus used for this purpose.

Plumbixan is a chemical compound representing the combination of a metallic plumbate salts of an alkali with a manganate, oxide of an alkali. For example, salts of a sodium basis and the following composition:

The idea of using a similar mixture is not entirely new and numerous tests in this direction have been made before, but when simple manganates are used they become soft during the period of evolution of oxygen, under the influence of high temperature and steam, and therefore lose more or less the porous state so essential for the evolution of a gas process; and as a result of that, the amount of gas given off gradually diminishes. As the author has found from his own experiments, this objectionable phenomenon is due to the formation or disassociation of hydrates of alkali which are evaporated through the action of the superheated steam. This secondary reaction destroys more and more the porous state of the material and the permanency of its chemical nature so that after a comparatively short time, it becomes necessary to introduce new material.

On the other hand, the manganates, on account of their

rapid and easy formation, when a mixture of their components is heated in the air, are extremely convenient for use as extractors of oxygen from the air. All that was necessary, was to obviate the above described objectionable feature by proper means, and the author found that he could attain that by an addition of a plumbate salt. At the same time, he had previously been able to establish that in the presence of basic materials and a high temperature, it takes up oxygen from the basic oxygen and passes into ortho-plumbate salts, which in their turn, under the influence of such hydrating materials as steam, are converted into meta-plumbates. Further, it is known that one of the general characteristics of plumbates is their ability to take up and give off basic oxides, and the author found that such would be just the right thing to take up the alkaloids from the manganates disassociated by water vapor and to reproduce them later on in a regenerating process. He actually found, on experimenting, that an addition of a metaplumbate and an alkali metal eliminated the vaporization of the alkali hydrate from the manganate and permitted the maintaining of the reaction material in a permanent working state.

The author describes in detail the respective chemical reactions and the construction of his apparatus. The Plumbixan process appears, from the description, to be quite simple. The air, after passing through cleaning chambers where it is freed from carbon dioxide, is driven by a blower, through a recuperator, into the main apparatus. After several minutes of regenerative action, the air current is shut off and practically simultaneously, the steam from a special boiler is admitted into the main apparatus where evolution of oxygen at once takes place. This oxygen is carried through the usual water seal system into a special gasometer.

As to the output obtained with this process, the data secured are only general. At 400 deg. cent. (752 deg. Fahr.), in 5 minutes approximately 1000 ccm. of oxygen are obtained from 1 kg. of Plumbixan provided the material is in a good porous state. At 450 deg. cent. (842 deg. Fahr.) 2000 ccm.; and at 500 deg. (932 deg. Fahr.) 3000 ccm. and more are obtained. It is of interest also to notice that as the temperature rises, the oxygen becomes purer. Since the oxygen during the regenerative process is taken up from the air by the salt combination, nearly pure nitrogen is obtained as a by-product of the process. Farther, the regeneration of Plumbixan by the air can be carried on at the same temperature as that of the evolution of oxygen.

The author discusses in considerable detail, the chemical part of the process and comes to the conclusion that catalysis plays an important part in this reaction. DESTRUCTION OF TIMBER BY MARINE BORERS, E. S. Christian.

Since marine borers do not thrive in foul water and prefer the uncontaminated water of the ocean, Hampton Roads offers an ideal environment for the growth of teredo and its kindred borers. In this connection, the author presents some data on the history of the Chesapeake and Ohio Pier No. 6, at Newport News, Va., on Hampton Roads, just below the mouth of the James River. It is interesting because in this case, timber treated with 12 lb. of Dead Oil per cubic foot has withstood the attacks of marine borers for 32 years, while timber not so treated lasts not more than two years and is sometimes destroyed after one summer season. Piles were treated and used in rebuilding that pier in 1883, the amount of the treatment required being that each of the piles absorbed 12 lb. of Dead Oil per cubic foot. One of the tests made to determine this was to bore each pile in six places and if any boring showed a penetration of less than 1½ in., the pile was rejected and treated again. The specifications under which the oil was bought called for not less than 60 per cent of naphthaline. The author believes, however, that in the treatment of cross ties and bridge timbers, the naphthaline fraction may be lower, provided that the percentage of pitch is increased; in view of the difficulty of obtaining oil with more than 35 per cent of naphthaline, he has lately recommended 16 lb. of oil per cubic foot for marine work in Hampton Roads. (9 pp., 8 figs. *dh.*)

ADDITIONAL FACTS ON TREATED TIES, J. H. Waterman.

The author presents data on ties treated by various processes.

In inspecting ties treated by Full Cell creosote process in experimental tracks on the Burlington Railroad, he found that a number of cotton-wood ties treated by this process, although softwood, are giving most excellent service and are in as good condition as any other ties treated by this process on the experimental track. Further, ties so treated do not rail-out as badly as ties treated with zinc chloride.

As to ties treated with zinc chloride (the Burnettizing process), the author found in going over a number of the Santa Fe lines and lines in Western Kansas that ties treated with this process have given very good results and that practically all of them gave nine years' life before they were removed. On the Illinois Central Railroad, the author found that ties treated with zinc chloride in 1904 were giving much better service than ties treated in 1907, but does not explain why.

On the Chicago and Eastern Illinois Railroad, the author saw ties treated by the Wellhouse process (zinc, glue and tannin). On that line, red oak ties so treated were

placed in track in 1900 and special dating nails were placed in each tie. By actual count, in June 1914, there were still remaining in the track about 75 per cent of the ties originally placed, thus giving them a 14 years' life; the author has even seen a number of red oak ties treated with the same process bearing dating nails of 1899—most of these ties being in a very good state of preservation.

Until the price of creosote was advanced, the Burlington Railroad treated their ties with the process known as the Card process (an emulsion of creosote and zinc). While a large number of ties so treated are laid in the experimental tracks of the Burlington Railroad, it is too early to draw any positive conclusions and one can only say that the ties treated with the creosote and zinc show less mechanical wear under the rails than those treated with straight zinc. It appears that the oil in the ties treated with the creosote and zinc is drawn to the surface and lubricates the tie under the rail which causes less rail end and surface wear and prevents the tie from checking. (7 pp., *ed.*)

A SPECIFICATION FOR A COAL TAR CREOSOTE SOLUTION,
Herman von Schrenck and Alfred L. Kammerer.

The authors give a specification for a coal tar creosote solution, the necessity for which arose from the fact that during the past year it has become somewhat difficult to obtain the usual supply of high grade foreign creosote, and there have been increasing inquiries for the mixture of coal tar and creosote. The writers, therefore, in coöperation with the Barrett Manufacturing Company, made a number of tests to determine the distilling points, specific gravity and viscosity of the various mixtures, by which they obtained the data given in a table in the paper. Based on this and similar determinations, they gave the following specification which is not regarded as final but only as an attempt to describe as briefly as possible an oil made up of coal tar and creosote with a certain percentage of coal tar:

The oil shall be a pure coal-tar product, consisting only of coal-tar distillates and oils obtained by the filtration of coal tar. It shall contain no admixture of crude tar. Water shall not exceed 2 per cent. Specific gravity at 38 deg. cent. shall not be less than 1.06 or more than 1.10. Matter insoluble on hot extraction with benzole shall not exceed 2 per cent. Viscosity (Engler) at 82.3 deg. cent. (180 deg. Fahr.) shall not be more than 59 for 200 c.c. No variation above 59 seconds shall be allowed. On distillation by the standard method of the A.R.E.A., it shall yield the following fractions, based on dry oil: Not more than 1 per cent at 170 deg. cent.; not more than 5 per cent at 210 deg. cent.; not more than 30 per cent at 235 deg. cent. The residue at 355 deg. cent. shall not exceed 26 per cent. (4 pp., *p.*)

CENTRAL RAILWAY CLUB

Official Proceedings, vol. 22, no. 5, November 1914, New York City

PAINTING OF STEEL CARS AND LOCOMOTIVE EQUIPMENT,
Milton L. Sims.

The methods of painting equipment of wooden construction would not be suitable for steel and the introduction of all steel equipment required the development of new methods based on an intimate acquaintance with paint pigments and vehicles.

The preparation of a steel coach for painting is of vital importance and demands close attention. It should never be left to inexperienced help and must be done thoroughly.

as the absolute removal of all scale, grease and corrosion is necessary before any protective coatings should be applied. Properly selected paint pigments combined with the proper vehicles will prevent the starting of corrosion, but the idea that paint coatings will stop corrosion when it has once started, is not correct. There are several methods for removing rust from steel, but the safest and most economical is sand blast for the outside of cars, while for the interior of a steel car, the speaker recommended the use of raw linseed oil and benzine or gasoline, in the proportion of one part of oil to two parts of benzine, applied with a brush and rubbed down with emery cloth or paper. The sheet steel used on the interior of cars is much lighter in weight and finer in texture and does not need sand blasting to obtain excellent results. After the rubbing down is completed, the surface should be washed with gasoline and wiped dry with rags or waste. It is then ready for the priming coat, which, in all cases, should be applied as soon as possible after the surface has been cleaned, especially in regard to the outside surfaces where the sand blasting process has been used, because when the atmosphere is damp or the humidity is heavy, corrosion will start up again in a few hours. Great care should be taken also to prevent the handling of the surface with naked hands.

The priming coat is very important and too much care cannot be exercised to see that it is done thoroughly, brushed out evenly and every bolt-head and joint coated perfectly, using suitable brushes for the purpose. The solid through trains, running from the ice and snow of the North to the tropical climate of the South, are especially liable to influences producing cracking and disintegration of paint and varnish films, on steel cars, much more than wooden ones. When the priming coat has dried sufficiently, the next step is to harden putty and to glaze coat over all the rough places, in which case the second coat or brush surfacer is used, which is designed to fit with the priming coat. This material must always be finely ground, and work and spread easily over the large surfaces. It must dry hard but elastic.

The next step is to apply a much heavier bodied surfacing material, which is then knifed off, leaving a very smooth surface, which requires much less rubbing to make it ready for the color coats. The old method of using block pumice stone and water is dispensed with and a more modern and safer method of rubbing the surfaces down smooth by using raw linseed oil and benzine in equal parts on emery cloth and then washing or wiping the surfaces off with clear benzine or gasoline on rags or waste. This method of surfacing does away with all danger from moisture and prevents the starting up of corrosion where sharp edges or bolt heads may be cut through the metal.

The paper describes further the application of body color, interior finish, the painting of floors, roofs, trucks and platforms and gives also the following schedules for painting the exterior of steel passenger coaches and locomotives:

SCHEDULE FOR PAINTING EXTERIOR OF PASSENGER COACHES

1st Day	Apply priming coat.
2nd "	Harden putty and glaze all rough and uneven parts of surface.
3rd "	Apply coat of brushing surfacer.
4th "	Apply coat of knifing surfacer.
5th "	Rub out with emery cloth, using half and half raw linseed oil and benzine, instead of block pumice stone and water.

6th "	Apply first coat of car body color enamel.
7th "	(If Sunday) drying.
8th "	Apply second coat of car body color.
9th "	Stripe and letter.
10th "	Apply first coat durable outside finishing varnish.
11th "	Drying.
12th "	Apply second coat of durable outside finishing varnish.
13th "	Car is completed.

SCHEDULE FOR PAINTING A LOCOMOTIVE

1st Day	Apply priming coat of special locomotive primer.
2nd "	Harden putty and glaze coat all rough and uneven surfaces. (This does not apply to trucks, frame work, etc.)
3rd "	Apply brushing and knifing surfacer to water tank or tender, cab, steam dome, sand box, etc.
4th "	Rub out surface with emery cloth, using half and half raw linseed oil and benzine. Wipe off dry with rags or waste and clear benzine, being careful not to use too much benzine. Follow up with coat of black enamel. On best work, a coat of flat black is applied over all surfaces, except trucks, frames, etc., before the black enamel coat is applied.
5th "	Letter and finish with a coat of durable locomotive finishing varnish.

Shorter and quicker methods are not reliable or recommended, except for re-painting and repair work. (30 pp., 3 figs., *pdf*.)

Action of Water in Locks of the Panama Canal, Col. H. F. Hodges

Percolation and Upward Pressure of Water, Capt. W. A. Mitchell (abstracted)

The Huai River Conservancy Project

PERCOLATION AND UPWARD PRESSURE OF WATER, Capt. W. A. Mitchell.

The paper considers the action of percolation and upward water pressure is as far as it affects the design of dams, and is to a large extent based on experimental work.

Very little information has been obtained so far as to upward pressure, and although it has been known for a long time that some provision for it was necessary, no accurate allowance has been made in the past. The author investigated three fundamental subjects—adhesion, percolation and upward water pressure, as affecting the design of dams and locks, mainly on the basis of experimental work done for this particular purpose by the Ohio River Board and others. The article, though of great interest, is too long to be fully abstracted and only the author's conclusions are here reproduced.

Little or no allowance can safely be made for adhesion of concrete to concrete or of concrete to rock.

Water pressure is transmitted through concrete, though quite slowly. If allowed free exit, this pressure is practically negligible.

Water pressure is transmitted through joints between con-

crete and concrete, and is transmitted more freely than through solid concrete. The water is transmitted quite slowly and if allowed free exit, the pressure is practically negligible.

Water pressure is transmitted through joints between concrete and rock. This is generally transmitted more freely than through joints between concrete and concrete. The amount varies with different rocks. The water is transmitted quite slowly in general and if allowed free exit, the pressure is practically negligible in good rock without cracks or fissures.

Water travels in small veins in the joints between concrete and concrete, and between concrete and rock. If allowed free exit, the pressure varies irregularly between upper and lower pools. If the exit is closed, the pressure quickly becomes that of upper pool, and water rises in test holes to level of upper pool as soon as enough water has passed through the veins to fill the test holes.

The amount of space of these small veins, that is, the area of upward water pressure, varies from nearly zero in excellent granite foundations to 50 per cent or more in rotten shale. It is practically impossible to calculate this.

Water pressure is transmitted more or less freely through washed sand, gravel aggregate, and washed river gravel and hardly at all through alluvial soil.

Puddled alluvial soil has practically no water pressure, if there are any drains, but such soil quickly disintegrates with a running leak.

With a material such as alluvial soil, which offers such a great resistance to percolation as practically to prevent it, a very small number of relief holes in the slab would be sufficient to eliminate almost the upward water pressure, provided, of course, that the material were such that only percolation and no erosion would take place.

With a material offering so great a resistance to percolation as washed sand, a very small number of relief holes would greatly reduce the upward water pressure when there is no outlet at the toe of the slab.

With a slab having a free exit for water at the toe, and a row of sheet piles at the heel, the upward water pressure varies from one-third the head at the heel to one-fourth the head at the toe.

Gravel aggregate offers less resistance to percolation than the river sand, and more than the river gravel. Hence, for the same reduction of upward water pressure when there is no outlet at the toe of the slab, more relief holes will be needed than for the sand and less than for the washed gravel.

For a slab having free exit for water at the toe and a row of sheet piles at the heel, the upward water pressure varies from one-sixteenth the head at the heel to one-fortieth the head at the toe.

In a material offering such a small resistance to percolation as washed gravel, a large number of relief holes in the slab will be necessary to reduce materially the upward water pressure when there is no outlet at the toe of the slab.

With an outlet for water at the toe of the slab and a row of sheet piles at the heel, the upward water pressure varies from full head at the heel to about one-third the head at the toe.

The pressure of water with free exit, transmitted through

sand, washed gravel, or gravel aggregate, is diminished greatly on entrance and more slowly, but surely, diminished along the line of travel.

Full upward pressure of water, without free exit, is transmitted quickly through washed gravel, and less quickly through gravel aggregate and sand.

Water percolates (very slowly) through concrete and rock. There is very little percolation through alluvial soil.

Water percolates more or less freely through sand, gravel aggregate, and washed gravel.

Water creates "boils" at the toe of the foundation after the relation of head to length of travel (percolation factor) becomes a certain amount, varying for different materials. This condition is dangerous to the foundation when the velocity of exit is sufficient to carry away with it the material of the foundation. It is generally best to make this percolation factor so great that there will be no such boils.

If the percolation factor is too small (varies for different materials) the material under the foundation will blow out and the foundation will fall in. With alluvial soil, this blow-out comes with little or no previous warning by boils. (50 pp., 34 figs., c.1).

INSTITUTION OF CIVIL ENGINEERS

Tests of Reinforced Concrete Structures on the Great Central Railway, J. B. Ball (abstracted)

Corrosion of Steel Wharves at Kowloon, S. H. Ellis (abstracted)

Concreting in Freezing Weather, and the Effect of Frost upon Concrete, John Hammersley-Heenan

TESTS OF REINFORCED CONCRETE STRUCTURES ON THE GREAT CENTRAL RAILWAY, J. B. Ball.

Data of tests of reinforced concrete structures on the Great Central Railway, such as an overbridge, a bridge carrying a new road and tramway, four high level railway bridges, and foundations and pits for engine shed.

In the case of the overbridge, the entire superstructure is reinforced with round bars on the Hennebique system; the abutments at each end are of mass concrete but the piers are braced and reinforced. Both tensile and compressive reinforcements were used in all the beams, the percentage of reinforcement in the main girders being exceptionally high on account of the area available in the compression flange. The bridge was tested with a dead load of 1 cwt. per square foot and a rolling load of two 16 ton traction engines, each hauling a lorry loaded with pig iron to a weight of 32 tons, or a total moving load of 96 tons. In all cases, the recovery was complete after the load was removed. The working stresses were limited to 700 lb. per sq. in. maximum compressive stress on the concrete, and 16,000 lb. per sq. in. tensile stress on the reinforcement.

In the reinforced concrete bridge carrying a road and a tramway for the Grimsby District Light Railway, the percentage of reinforcement ranges from 0.60 per cent in the cross beams to 4.67 per cent in the outer main beams of the longer span. The bridge was tested with two moving trams and no appreciable deflection was reported on any of the beams. It was designed to allow for the passage of two 40 ton boiler-trolleys drawn by a 5 ton traction engine, the portion of the bridge not covered by moving loads being loaded with 1 cwt. per square foot. In computing the stress, the various members were taken as being freely supported

and no allowance was made for the continuity of the beams, or for the fixity of the ends, the allowable working stress being the same as in the case of the previous bridge.

In the reinforced concrete foundations and pits for the engine shed at Inningham dock, the work consists of a reinforced concrete raft so spread that the load upon the ground nowhere exceeds 10 cwt. per square foot, and the engine pits form part of the raft. Reinforced tie beams are provided every 60 ft. between the pits, and Kalm bars are used throughout in the reinforcements of this work. (4 pp. d).

CORROSION OF STEEL WHARVES AT KOWLOON, S. H. Ellis.

Description of steel wharves at Kowloon, Hong Kong Harbor, British possessions in China, and the corrosion of same.

In 1906, in connection with the reconstruction of a wharf

this process is started, the deposit of sulphide favors more rapid corrosion beneath it. The destructive effects of this kind appear to be confined to the part between low water level and 15 ft. below it, the zone of the worst corrosion extending from 5 ft. to 10 ft. below low water level.

It was eventually decided to increase the whole of the new structure in concrete and have the other wharves bare steel painted with anticorrosive composition on erection. Since this was done the superstructure and the piles above low water level have been scraped and painted annually and the steel has been kept in fair condition with no mark of deterioration except once, when a longer period than twelve months was allowed to elapse between recoatings. The

FIG. 7. FAN TEST CURVES AND WATER GAGES

an examination was made of some steel piles, which had been in place for about four years, and they were found to be corroded in a curious manner. Any steel immersed in sea water at Hong Kong becomes quickly coated with barnacles and other shell-fish, and with a dense vegetable growth, particularly very near the surface of the water down to 15 ft. or so below it. It has been an accepted theory that this growth protects the metal and prevents rusting, but when the growth which had been scraped away from the pile was examined, it was found that a large number of pits had formed in the surface of the steel varying in size up to $1\frac{1}{4}$ in. in diameter and 3 in. deep. They were found full of a black carbonaceous powder, which was found also in a thin layer on the surface of the unpitted steel and, on exposure to the air turned to a dark red color. On analysis, it was found to be sulphide of iron and its change of color was due to oxidation. Apparently some particular shell-fish or marine growth attached to the piles produces large quantities of sulphide of hydrogen when dead and decayed, and this sulphide of hydrogen attacks the metal. It is evident that when once

yearly cost of maintenance is about £100 for a total deck area of 34,000 sq. ft. Two years after completion, pitting had commenced on the under water surface of the piles, the construction coating of paint having then almost disappeared and a thick layer of shells and marine growth had become attached to the metal.

The author describes in detail the method used in increasing the piles with concrete, a minimum cover of $2\frac{1}{2}$ in. of Portland cement concrete of standard quality being provided to the steel throughout. After the whole of the work had been completed about a year, and the bulk of it for about two years, the author made an inspection of the wharf and was unable to detect any sign of deterioration on the surface, but he did not cut into the concrete. Three years later obvious indications of corrosion within became apparent on the surface of the concrete and a thorough examination of the whole structure revealed that above high water level corrosion appeared to have gone on almost unchecked by the presence of the concrete covering, and a thickness of about 1.46 in. of rust scale was found on all the steel members in this zone on their under and outer sides.

The author concludes that while steel protected by concrete has little or no tendency to corrode if it becomes thoroughly wet twice in the twenty-four years, yet when it is continually exposed to air damp from the evaporation of sea water, especially in a tropical climate, some other external coating must be sought, either as an addition to the concrete or in place of it. Curiously enough the corrosive effects of damp salt air appear to be limited to a zone immediately above the surface of the water. Steel work, both exposed and embedded in concrete, in warehouses on the same property has not been found to be affected.

THE TESTING OF FANS, WITH SPECIAL REFERENCE TO THE MEASUREMENT OF PRESSURE, Thomas Bryson.

Discussion of the question of reliability of fan tests and determination of various factors in the expression of mechanical efficiency with special respect to the exact determination of the height of the water gage.

The writer bases his specification for a water gage on the principle of conservation of energy as applied to measurement of pressure and proceeds to the discussion of the position and form of the water gage. While it is generally agreed that the water gage should, in addition to being placed at the entrance to the fan, be measured also at the ear of the fan, there is nothing unanimous with regard to its precise position. If *D*, Fig. 7A, be the correct form, it may be placed anywhere near the fan—even in the ear of the fan, but if *C* be used, it may be most conveniently placed near the ear of the fan on the wall of the drift. If the gage be placed in the ear of the fan, error is bound to arise from varying velocities, due to eddying currents, but if a gage of the form *C* be placed on the wall of the drift near the fan, and separated from the drift by a partition in which there is a capillary connection, it is most likely that the pressure registered will be effected by air currents, since the interior of the box will be a zone of reduced pressure in which there would be no appreciable movement of the air. The condition of the air in the box will be quite the same as that of the air at section *C* in the drift (Fig. B); consequently, a gage of the ordinary form, fitted to such a box, would register exhaustion only.

The writer has recently made some experiments to test his conclusions with regard to the various forms of water gages. The following data are typical of the results obtained: Experiment No. 1 was carried out for the purpose of determining what pressures would be registered by gages of the forms *A*, *B*, *C* and *D*, attached to the fan drift, when no air was allowed to pass through the fan drift, it being closed at the end. Relative position of the fan, fan drift and gage are shown in Fig. C. The results obtained after a number of speeds of the fan are shown in a table. Another series of experiments was made to establish a relationship between gages of the forms *A*, *C* and *D* for the various velocities of the air passing the drift. A constant opening was maintained at the end of the drift, the change

of velocity being obtained by altering the speed of the ventilator. The results of this test can be seen from the curves in Fig. D. In the third series of tests, pressures were registered over a greater range of velocities than in the preceding series and the opening at the end of the drift varied, in order to obtain a series of "equivalent orifices." The results from this experiment are given in the original article in the form of a table, and are shown here by the curves in Fig. E.

From these tests, it appeared that at least three forms of the tube terminations *A*, *B* and *D*, were not scientifically correct. It was shown that the value of P_2 (Fig. B) at section *C* would be greater than either P_1 or P_2 at sections *A* and *B* respectively. Further, pressure registered by a water gage situated in the zone of reduced pressure, separated from the fan drift by a partition having a capillary connection in it, is greater than the section registered by a Pitot tube. If, however, the velocities are small, there is little difference between the readings given by *C* and *D*, but there is considerable difference between them at high velocities such

FIG. 8. DIAGRAM OF A SHAFT GOVERNOR

as 960 revolutions of the fan per minute, and velocity of air 1,600 ft. per minute.

In the discussion which followed, Wm. Davidson of Glasgow stated that recently he had had the experience of doubling the quantity of air in a mine by putting down a larger fan and when the fan was tested, in the first instance, difficulty was experienced in finding the proper water gage. No matter how the end of the tube was placed in the fan drift, there were different readings, indicating that something was wrong with the method. A method similar to that described in the above paper, however, was the only one tried. A steady reading was obtained and it was from that reading that the figures were worked out for the new fan. In building a fan drift for the new ventilator, a small manhole was inserted in the side with a steel door, having very small perforations. The end of the water gage was turned into that. The results from the new fan were very satisfactory. (6 pp., 5 figs. e.)

KYOTO IMPERIAL UNIVERSITY, COLLEGE OF ENGINEERING

Memoirs, vol. 1, no. 1, August 1914, Kyoto, Japan

DISTURBING ACTIONS OF A SHAFT GOVERNOR, Genjiro Hanabe.

The paper is devoted to a consideration of the disturbing actions of a shaft governor applied to a steam engine as its

speed regulator. It reports an investigation of the laws of these disturbing motions, considers the static conditions of the governor and gives a method of designing it in connection therewith.

In the case of a conical pendulum governor, the forces at the sleeve required for overcoming the resistance of the regulating gear when a movement of the sleeve is commenced, may be regarded as constant in magnitude. The case is quite different in a shaft governor. Most shaft governors in practical use are attached to the fly-wheel, the eccentric disk being held in position by the governor and on this account, a comparatively large amount of the resistance of the valve gear continually reacts on the governor. Fluctuating and reversing periodically, according to the position of the crank, these forces cause the pendulum of the governor to vibrate about its position of equilibrium and this vibratory motion may cause a false distribution of steam. Further, when the load on the engine is altered, the relative configuration of the governor changes accordingly and the pendulum moves from one position of equilibrium to another.

On account of the inertia of the pendulum and the parts connected therewith, this change of configuration is sometimes accompanied by a number of vibratory motions which cause a serious disturbance of steam distribution. Fig. 8 is a diagrammatic sketch of a shaft governor showing about one-half of the governor. It is attached to and rotates as usual with the crank shaft O , consisting of a pair of pendulums arranged symmetrically with respect to O , with its fulcrum at S and its center of gravity at P ; a spring F attached at G and passing through O connects the pendulums. There is a centrifugal force C at each pendulum so as to throw it out against the force of the spring F . The pendulum has a lever SQ on the opposite side of S and the end Q of this lever is connected with the eccentric center E by means of a rod QE . In order to keep the lead of the valve constant, the eccentric center is assumed to be guided so as to move along a straight line AB , perpendicular to the center line of the crank. After the engine is unloaded, either suddenly or gradually, the speed of the engine increases, the pendulum flies out owing to the corresponding increase of the centrifugal force and the steam is cut off earlier than would have been otherwise the case.

If there were no vibratory motions of the governor, the pendulum would be at rest with respect to the flywheel in a steady working condition of the engine; consequently all moments of force, acting at several points of the pendulum would be in equilibrium and for the equilibrium of the pendulum about this fulcrum S , the following three moments must form a balancing set: the moment of the centrifugal force of the pendulum acting clockwise; the moment of force of the spring acting counter-clockwise and the moment of the mean reacting force of the valve gear acting counter-clockwise. The first moment depends on the angular velocity and the position of the pendulum; the second and third moments, on the position of the pendulum only. The author gives equations for the determination of these three moments as well as an equation of the state of equilibrium of the governor, and from this equation can be found the values of the moment of centrifugal force of the pendulum at different positions and the characteristic curve of the governor can be drawn. The irregularity of the governor can be found from the curve. Conversely, assuming the

value of principal irregularity of the governor, we can determine the dimensions of the governor spring from the equation.

The author gives examples of the application of these equations, such as that of a vertical single cylinder 10 in. x 10 in. fitted with a piston valve 4.33 in. in diameter, running at 240 r.p.m., under a pressure of 6 atmospheres absolute and regulated by a shaft governor mounted on the crank shaft. He goes through the entire calculation and gives the characteristic curves of the governors which, under certain limitations, would be used on such an engine. This part of the article is not suitable for abstracting.

He proceeds then to an investigation of the vibration of the pendulum caused by periodic changes of the reacting forces of the valve gear, and treats the subject in a strictly mathematical manner. From the results of calculation he finds that the vibration of the pendulum caused by the reacting forces of the valve gear rises to a degree which is inadmissible in a regulator. If one tries, as with the conical governor, to make the "energy" so great that reacting forces may be inappreciable, a disproportionately heavier governor is necessitated and we have to remain content with the governor accompanied by vibrations which are damped in practice by frictional resistance at pins or at knife edges which was not taken into account in the deduction of the equation of motion; or some device must be perfected whereby to suppress these vibrations. Since in a conical governor the chief source of vibrations is the unsteadiness due to the finite mass of the flywheel, they may be removed by fulfilling the condition that the insensibility of the governor should not be less than the unsteadiness of the flywheel, but in a shaft governor, which is a pure spring governor, the vibrations are caused by the reacting forces as well as by the influence of the unsteadiness of the flywheel and meeting only the latter condition, would not sufficiently remedy the evil. To obviate this, a shaft governor is often provided with a dash pot or oil brake.

The author next investigates the mechanical motion of the pendulum when the load on the engine changes and finds the equations which show this. In several examples, he shows the manner in which the governors approach their new position of equilibrium, some of them coming to it sooner or later with the approaching motion accompanied or not by some oscillation, but without any over regulation at all, while in all other cases, the governors make over regulation in different degrees, all, however, come practically to rest after some interval of time in the new position of equilibrium. On the whole, the author concludes that the governors which are found by means of their characteristic curves to be stable, do not necessarily come to their new position of equilibrium. In other words, a governor not fulfilling the conditions established by one of the equations found by the author and having no constant friction is of an unsteady character, while some governors may be defective on account of over regulation or hunting. Moreover, if a governor be constructed so as to obviate these defects, too steady a governor may result, which requires a longer time for its displacement; such a governor is again unfit for practical use.

An interesting part of the above paper not presented in the abstract is the mathematical treatment of the subject and the characteristic curves of the governors reproduced in the paper.

Charging of Two-Cycle Engines, Professor B. Hopkinson (abstracted)

A New Type of Internal Combustion Engine, H. F. Fullagar (abstracted)

THE CHARGING OF TWO-CYCLE INTERNAL COMBUSTION
ENGINES, B. Hopkinson.

The paper discusses the subject of charging of two-cycle internal combustion engines and takes up the effect of stratification on the performance of the engine. It includes also tests on the Fullagar engine.

The performance of two-cycle internal combustion engines is determined very largely by the efficiency of the process of charging. In view of the very short time given for replacing the gases of combustion by a fresh charge, some mixing in-

contained in the exhaust gases at the point close to the ports at any stage of the charging (z is not the volumetric proportion determined by ordinary analysis but the volume reckoned at atmospheric pressure and at the temperature of the air as it comes in, contained in a cubic foot, the balance of $1-z$ consisting of burned products from the previous explosion, whose volume is for this purpose reckoned at the temperature of those products before charging began). Obviously z will increase from zero as the charging goes on and will approach but never reach the value unity. The total amount of air lost in charging will be equal to the volume delivered, z , multiplied by the average value of z and is readily calculable if this quantity is known at every stage. The mass of air retained in the cylinder is equal to y minus the loss, and this will be denoted by x .

Two cases admit of very simple treatment. The first is the ideal case of perfect stratification where the air simply drives the burnt gases before it without mixing with them at all and there is no loss at all until the amount of air exceeds the cylinder volume,—a condition which is never even approached in practice; and the second case is more nearly what actually happens,—instead of complete stratification there is no stratification at all, mixing being so complete that the cylinder contents are at every instant of uniform composition throughout. Here the quantity z represents not only the proportion of air in the gas which is going into the exhaust at any stage, but also the proportion then present in the cylinder as a whole. For the sake of convenience, as unit of volume, is taken the whole of the cylinder volume of air maintained in the cylinder, which also represents the proportion of air in the whole cylinder contents so that in the case now under consideration z equals x . In Fig. 9, x is plotted against y , the amount (in cylinder volume) of air which has been injected. When the amount ON has been injected, the air present in the cylinder is PN , the remainder PN being the burned products. The effect of adding the further dose of air NN' is to expel at the exhaust, the quantity of air $\frac{PN}{MN} \times NN'$. The balance remains in the cylinder, increasing the quantity of air there by $P'Q = PM$.

$MN < NN'$, and the curve can be constructed in this way step by step. It is an exponential curve, whose slope at any point is equal to the ordinate PM . The relation between x and y is $X = 1 - e^y$. In short stroke Diesel engines with valves in the cylinder cover, the mixing is probably fairly complete. In engines having relatively longer cylinders, there is some stratification of the cylinder, but even there, not very much.

The main tests of the author were made on the Fullagar engine (described in the next abstract). In it, the air ports communicated with a large receiver to which air was delivered by an electrically driven fan. Coal gas was used in these trials and was admitted by a piston valve at the center of the cylinder, being delivered at high pressure by a reciprocating pump. For the verification of the formula above given were required the accurate measurements of, first, the total capacity of air delivered to the engine per minute and, second, the proportion of that air retained in the cylinder. To measure the quantity of air, a diaphragm with a circular hole was inserted in the air delivery pipe between the fan and the engine and the drop of pressure was measured by

FIG. 9. CHARGING CURVES OF FULLAGAR ENGINE

evitably takes place and some of the fresh charge or of the scavenger air passes away to the exhaust and is wasted. The waste of fuel affects the economy of the engine as well as the size of the charging pumps, which must be large enough to deliver the whole charge of gas and air, including that which is wasted.

The author stated that he was struck by the almost complete absence of data of general application on which to base, in the case of a new design, the calculation of the size of pumps required to give a certain mean pressure and a prediction of the economy which may be expected. Little or nothing has been published as to the amount of the loss to exhaust which occurs in exhausting engines, and there is no theory to guide designers in the use of such data as exist on this point or may become available.

In the course of the charging process, for each unit of volume of air or mixture which enters at the inlet, an equal volume of the gas near to the exhaust ports will be driven out through those ports. The gas will consist partly of burned products and partly of air which is mixed with the products. Denote by z , the proportion of air by volume

means of a water gage. The diameter of the air pipe was 18 in.; that of the hole in the diaphragm 9 in. The current of air through the diaphragm was nearly uniform because of the pulsations of the engine being nearly damped out by the large air receiver. The velocity of the air through the hole was calculated according to the usual formula, assuming 0.62 as the coefficient of discharge. The author believes that the quantity of air delivered to the engine was probably determined correctly within three per cent; the coal gas was also metered.

For determining the proportion of air retained, samples were taken of the contents of all four cylinders and analyzed. After absorbing the CO_2 the combustion of the residue was completed over palladium and the further yield of CO_2 obtained. The total CO_2 gave the proportion of coal gas to air in the cylinder contents. Simultaneous analyses of the exhaust gases gave the proportion of coal gas to air delivered to the engine, a check being obtained by estimating the oxygen in the exhaust and in the cylinder contents. The results obtained showed that there is a rough agreement between the calculated and measured figures—sufficient at any rate to justify the use of the simple supposition of complete mixing as the first approximation of what occurs. On the other hand, the deviation with smaller amounts of air is too great to be ascribed to errors of observation, the observed loss of air being only about two-thirds of the calculated loss which shows that there are disturbing factors which must be taken into account as corrections to this simple theory. One of such factors is the effect of stratification, the portions near the exhaust ports being poorer in air and richer in burned products than the average. In addition to that, there is also in all cases some throttling in the exhaust ports and exhaust pipe as well as inertia effects in the exhaust pipe in consequence of which the pressure in the cylinder varies during the admission period.

In the discussion which followed and which referred to both papers (Professor Hopkinson's and Mr. Fullagar's), Mr. J. W. B. Stokes pointed out that the waste of charging air is a field which cannot very well be avoided. If it were attempted to cut down this charge of air to the minimum quantity or to have no loss at all,—at any rate through the exhaust ports,—there would be a very great danger of some of the fresh gas making contact with the products of combustion, which would lead to a back fire. Therefore, for the safe working of the engine, scavenging becomes necessary. He described an experiment he tried with an engine in which the air loss was cut down to the lowest possible figure,—in fact, there was no scavenging air sent forward at all, but it was touch and go with explosions at the right moment of pre-ignition. The speaker further objected to the measurement of air in Professor Hopkinson's experiment by means of a diaphragm, as a possible error might be nearer 30 per cent than 3 per cent. In regard to the discontinuance of building the Oechelhauser engines by William Beardmore & Sons Company, Ltd., of Glasgow, which attracted considerable attention in England, the speaker, who is connected with that firm, stated that the reason for this was not that the engine was unreliable but that it cost too much to build it.

Alan E. L. Chorlton expressed his disappointment at the fact that Professor Hopkinson did not give any particular data taken from engines actually in use. He objected also to the statement that the imperfection of the charging process

was probably in a large measure responsible for the fact that 2-stroke engines have been unable to compete successfully in small sizes, with the 4-stroke cycle, and believes that there are not sufficient data available to make such a broad statement. (30 pp., 6 figs. *ed.*)

A NEW TYPE OF INTERNAL COMBUSTION ENGINE, H. F. Fullagar.

Description, somewhat incomplete, of the construction and operation of the Fullagar gas engine.

The Fullagar engine has been designed to overcome the

FIG. 10. FULLAGAR ENGINE

difficulties which are claimed to be in the way of increasing the size of gas engines: first, that the heat per unit of surface radiated by the flame to the cylinder walls increases with the size of the cylinder, while the thickness of the metal through which this heat has to reach the cooling water also increases; second, that the weight per h.p. increases with the size of the cylinder, and third, that the useless forces are called into play (useless in that they are either stationary

and do no work or even produce negative work). The Fullagar engine shown in Figs. 10 A and B, uses as a unit two open-ended cylinders, side by side, each with two pistons, and rigidly connects *A* to *D* and *C* to *B* by means of pairs of oblique rods external to the cylinder.

The action of the engine is as follows: when an explosion takes place between *A* and *B*, it drives *B* down and *A* up, drawing up *D* by the oblique rods, and giving, through the two connecting rods, two equal and opposite impulses to the cranks. The obliquity of the rods is small,—less than the obliquity of the connecting rods, so that the friction is actually less than would be the case if each piston had its own crank and connecting rods, and the mechanical efficiency of the engine is high. At the end of their strokes, the pistons uncover inlet and exhaust ports in the cylinder walls,—the engine working on the two-stroke cycle. Air is supplied to the cylinder by low pressure air pumps which can be driven from the engine by side levers in the ordinary way. In engines of the light high speed type, the upper cross-heads and guides are formed to act as air pumps, thus effecting a further saving of space and width. Stationary engines will usually comprise two units, making four cylinders, while more cylinders may be added for very large powers or where the height is limited.

With this construction, it is claimed that useless forces are avoided or at least greatly reduced. There are no cylinder covers nor any high pressure joints in the engine; no vertical stresses on the framing of the engine at all, the pressure of the explosion being entirely taken between the steel bars shown in Fig. B, the cross-head, oblique rods, connecting rods and crank shaft, and only the secondary reactions of the slippers, from 1.5 to 1.20 of the explosion forces, reach the framing of the engine in a horizontal direction.

The fluid pressure in each cylinder acts at every moment equally on the two cranks and the main bearings are thus relieved of practically all load except for the weight of the parts. The action of the explosion in driving apart the pistons *A* and *B*, drawn together by means of the oblique rods, the pistons *C* and *D*, compressing the charge between them so that the negative work of compression is performed not through the cranks and connecting rods but directly through the oblique rods and only the net useful work is transmitted to the crank shaft. Further, as each stroke includes compression and explosion, the reciprocating parts are cushioned at each end of every stroke, the combined effect of ignition and cushioning having for their purpose the keeping of the oblique rods in constant tension as well as making the crank effort more uniform.

The balance of the engine is practically perfect. The center of gravity of a pair of pistons, Figs. B, *A* and *D* for instance, is at the point *P* and moves up and down on the line *PQ*, while the center of gravity of the other pair is at the point *Q* and moves down and up on the same line. The author claims that this is probably the only engine in which the centers of gravity of the balancing masses have the same identical locus. If the forces working in this mechanism be divided into two rough classes, which, for the purpose of brief description, the author calls "useful" and "useless," the only ones falling into the latter class are the minor reactions from the slippers at the end of the oblique rods, constant in direction and less, both in number and amount,

than the similar reactions of any other reciprocating engine in common use, whether gas or steam.

In regard to weight, the new construction, by combining eight two-stroke pistons with four cranks, produces a given power upon $\frac{1}{2}$ to $\frac{1}{3}$ the weight required with other constructions. From a heat point of view, the double type of cylinder has material advantages, and further, such cylinders require but one crank each. In form, the cylinder is a plain tube, supported at either end but free to expand axially and with its fellows is surrounded by a common tank forming the water jacket. In such a cylinder, temperature stresses cannot occur and moreover, in the absence of corners or pockets, the actual mean temperature of the inner surface of the cylinder is very low.

To test the system, an engine of 500 h.p. was built and installed in the engine room of the Newcastle Electric Supply Company. It is of the stationary type and weighs, without the flywheel, under 20 tons. As it develops continuously some 550 b.h.p., its weight is less than one-half of that of gas engines of equal power. A very interesting feature is the ease of repairs. An upper piston can be withdrawn in ten minutes after stopping the engine and the lower piston lifted out through the cylinder in three minutes more. The whole of the eight pistons can be withdrawn in an hour with the use of a hand crane only. In spite of the fact that the air and gas supply auxiliaries are somewhat of a makeshift in character, the over-all efficiency during a 30 hour test was found by Professor Hopkinson to be just under 30 per cent, with the indicated efficiency 37.6 per cent, and the mechanical efficiency about 90 per cent. The chief interest of the system is claimed to be in the promise it holds out of much larger powers with fewer and lower stresses.

In the discussion which followed, Richard W. Alan took up the question of the use of oblique rods in the Fullagar engine. At first, he was somewhat uncertain about the vibration of the rods and in order to safeguard against any accident which might arise out of these oblique rods, a special form has been constructed in which the rods were placed both with the top and bottom pistons; a hydraulic pressure of 50 tons applied to the rods gave only an extremely small deflection. To insure freedom from vibration, vertical guides have been placed on the oblique rods, which have a damping effect and in actual practice they experience no trouble whatever.

UNIVERSITY OF ILLINOIS

THE ANALYSIS OF COAL WITH PHENOL AS A SOLVENT, S. W. Parr and H. F. Hadley.

Report of work done at the Engineering Experiment Station of the University of Illinois, treating of a method of coal analysis in which the cellulose and resinic substances are separated by means of a solvent, the main solvent used in this investigation was phenol. While the paper does not contain a regular bibliography in the subject, it gives numerous references to previous investigations and an interesting historical sketch of coal analysis.

The purpose of this method of analysis is to separate in unaltered form the fundamental substances of which coal is composed and to study their characteristic properties in detail. By this means, it has become possible to study separately the insoluble residue and the extracted matter; to de-

termine which has the greater avidity for oxygen, and to which division belong the coking constituents and special products of decomposition, such as gas, illuminants and tar.

This is therefore of particular importance to the gas and coal tar products industries.

It was found that phenol at 212 deg. Fahr. will dissolve constituents of bituminous coals in their natural states and that the two sub-divisions designated respectively as insoluble residue and extracted matter together make substantially 100 per cent of the amount of the original substance. Studies upon these two type substances indicate that the extract is the vital constituent concerned in the coking of coal, that it has a sufficiently definite melting point, and a decomposition temperature which is above that of the melting point.

Each sub-division is capable of absorbing oxygen, but the insoluble portion has the greater avidity for it. The effect of absorbing oxygen upon the extract is to modify its coking properties by lowering or greatly reducing its power to form a firm and coherent mass. The oxygen taken up in either

case is found to be chemically combined and the oxygen taken up by fresh coal is similarly held.

Previous work has shown that oxidation was playing an important role in producing changes in the residue and extract. It was desired, therefore, to establish whether the loss of coking properties was due to oxidation or simple absorption of oxygen as well as to see what effect the heating at 105 deg. cent. (221 deg. Fahr.) would have on the percentage of volatile matter. Coal was heated therefore in air at the above temperature for different lengths of time and volatile matter determinations were made at successive stages of oxidation, and it was found that the volatile matter decreased with progressive heating and that the decrease in volatile matter was more rapid in the case of the coal which had the higher percentage in the beginning. It was found also that residue and extract possess an avidity for oxygen, the residue showing the greater avidity. The ultimate analysis of the coal residue and extract show that the percentages in both of carbon, hydrogen, nitrogen and oxygen are substantially the same. (41 pp., 6 figs. *cp.*)

SOCIETY AND LIBRARY AFFAIRS

MEETINGS

BOSTON, JANUARY 6

The meeting of the Boston Section on January 6 was devoted to the subject of Aviation. Albert Adams Merrill discussed the problem of fore and aft stability. He said that as long ago as 1871, the French aviator, M. Penaud, had shown the value of the longitudinal dihedral, composed of two surfaces, the front one being the main supporting surface and the rear one being a non-lifting tail. The dihedral was obtained by making the angle of incidence of the front surface greater than the angle of incidence of the tail, which in the Penaud models had a negative angle.

The trouble with all cambered surfaces is that the center of pressure moves in the wrong direction with a change in the angle of incidence within the limits of flying angles, but by using two surfaces with a longitudinal dihedral between them, the movement of the center of pressure of the system can be altered so as to get any desired movement. Practically all machines get their dihedral between the supporting surfaces and a non-lifting tail. Mr. Merrill claims this is not the best way for two reasons. First, because the tail is not a weight carrier and hence wastes power, and second, because the horizontal gap between the tail and the main surface produces a time lag in the introduction of the righting couple which is bound to set up oscillations about the lateral axis. To overcome this, Mr. Merrill designed a biplane in which the top surface is ahead of the lower surface and the chords are not parallel, the angle of the front being greater than that of the rear. Such a machine is called a converging staggered biplane. With this design the dihedral exists between the two supporting surfaces and no tail is necessary. Such a machine was built and flown during the last summer, first as a land machine and then over water. With this design, it is possible to get any desired movement of the center of pressure

of the system. Mr. Merrill illustrated his talk with black-board designs and small paper flying models.

Greedy S. Curtis, of the Burgess Company of Marblehead, presented a number of interesting slides showing aeroplanes in flight and also showed a number of charts. He mentioned that during 1914, there had been little advance in speed or duration of flight, the speed record standing at approximately 123 miles per hour. In regard to inherent stability, many experiments had been made with the Dume machine and with the Dume-Burgess type at Marblehead, which practically eliminate stalling and diving and require but little manipulation of hand control levers governing the stability. Mr. Curtis showed cuts of the Sperry gyroscope stabilizer.

Prof. Joseph C. Riley, of the Massachusetts Institute of Technology, showed many lantern slides of gasoline engines including four, six and eight cylinder models. He stated that a four cylinder model won the foreign competition prize in 1912 for a seven hour test. Later in the British competition, no engine with less than six cylinders was allowed to enter. He called particular attention to the Benz engine which has proved so economical. He pointed out the trouble in balancing a four cylinder engine to do away with vibration and called attention to the advantages of six and eight cylinder designs. He also showed illustrations of the rotary types and mentioning particularly the Gnome.

The attendance at this meeting was about 125.

BUFFALO, JANUARY 7

A meeting of the Buffalo Engineering Society was held on January 7. The meeting was addressed by Prof. J. A. Moyer of the Pennsylvania State College who spoke on Recent Development in Steam Turbine Engineering. After giving somewhat of a history of the early development of the steam engine, he gave a full and complete explanation of the new mercury turbine which is now being developed at Schenectady. There was some spirited discussion of

Prof. Moyer's paper. The attendance at the meeting was about 160.

CHICAGO, JANUARY 8

A meeting of the Chicago Section to which the members of the Western Railway Club were invited was held on January 8. The speakers of the evening were R. M. Ostermann and Clement F. Street who covered the subjects of superheaters and mechanical stokers respectively and Willard A. Smith, president of the Railway Review, who spoke of Railway Economics.

In discussing superheaters, Mr. Ostermann explained concisely, with the aid of stereopticon views, the construction of the superheater and cited by means of diagrams, the results of tests showing the nature and extent of the economies derived from the use of this apparatus.

Robert Quayle discussed the superheater experience of the Chicago and Northwestern Railway which has in use, 425 superheater locomotives. From the shop and round house point of view, importance was laid on the possibility of suppressing steam leaks and keeping the flues open for the ready passage of the gases around the superheater units. An experimental equipment containing a pyrometer has been installed in some cases indicating to the men in the cabs, the temperature of the steam at all times passing through the cylinders, and in this way suggesting such defects in manipulation as holes through the fire, excessive thickness of fuel bed, steam leaks in the front end or in the operative damper. In regard to lubrication, difficulties have been overcome to a large extent by getting the engine-men into the habit of running on cracked throttle whenever the engine is not running under power, and this made possible the general return to the usual grades of valve oil instead of the more expensive kinds that at first were thought necessary. While the fuel savings vary with the intelligence and alertness of the engine crews, on the average they are believed to amount to twenty per cent of the amount required by non-superheater engines. The saving in water consumption was such that switchers were found to be able to work nearly fifty per cent longer on a given amount of water than they did before superheaters were applied.

The boiler pressures now prevailing on superheater locomotives of the Chicago and Northwestern Railway are thirty pounds less than on the non-superheater motive power and this together with the adopted practice of regularly assigning crews to engines may have been the cause of the fact that the direct maintenance expense was found not to be appreciably greater than similar expense on the non-superheater class. Superheater equipment has also proved very popular with the men.

In regard to mechanical stokers, Mr. Street spoke of the magnitude of the railway industry and the influence exercised on it by the efficiency movement in the use of the coal in the firebox of the locomotive.

II. T. Bentley of the Chicago and Northwestern Railway stated that his road has not yet felt a real necessity for stoker equipment partly because its locomotives are relatively small and also on account of the fact that the labor of the firemen has been greatly reduced through the use of coal pushers, for the purpose of delivering the coal to the forward end of the tender and within easy reach of the firing deck.

This was followed by a series of answers given by Mr.

Street to questions raised by the audience. One of the statements made in this way was that by the use of the stoker in one instance, slack at 60 to 75 cents per ton has been successfully fired in competition with run of mine, hand fired, costing from \$1.20 to \$1.50 per ton, and at the same time with improvements to the ability to handle traffic.

In the discussion of the subject of Railway Economics, Willard A. Smith, of the Railway Review, Chicago, cited the evident trend of affairs in regard to maintenance of equipment costs resulting from the extended use of high capacity cars and locomotives. Numerous figures were cited to indicate this condition, not the least impressive of these was that had a reduction of ten per cent been made in the maintenance of equipment costs on the roads of this country for the last fiscal year, it would have made possible the doubling of the dividends paid and also that were the seemingly plausible saving of 20 per cent to be made in the maintenance of equipment costs on the basis of last year's returns, the dividends could be quadrupled. At the rate maintenance of equipment expense has been increasing during the past ten years, it is to be anticipated that in five years, this item will represent as large an expenditure as does operating expense. On some roads, maintenance of equipment costs already exceed those of operation. On other roads this expense is greater than the entire passenger revenue. On others, locomotive maintenance alone costs 25 per cent more than those roads expend for fuel. Since 1900 the average tractive power of locomotives has increased 36 per cent while the cost of maintenance to those locomotives has increased 93 per cent. The average freight car capacity in the same period has increased 34 per cent, the average load 28 per cent, while the freight car maintenance costs have advanced 67 per cent. Freight car maintenance costs have so far advanced that they now amount to approximately two and one-third times fuel and locomotive maintenance costs combined.

As a possible means of solution to the problem which the railroads are confronting in this connection, it was suggested by Mr. Smith that there be established a national bureau of railway engineering whose functions would be to investigate conditions as to nature and capacity of equipment, roadbed, terminal facilities, etc., and render to the roads seeking its services such recommendations in each case as the country's best engineering, and administrative talent and experience could afford. In Mr. Smith's opinion, a bureau of this nature might properly be established in one of three ways, enumerated herewith in the order of their preference: First, a governmental bureau, for which ample precedence is afforded in the Department of Agriculture and in the Bureau of Mines; second, by private endowment, an action which not a few individuals or establishments having achieved their success through the patronage of the roads of this country, could well afford to take with lasting benefit to the roads and distinction for themselves; and third, through a commission to be created by the roads on their own responsibility, to be supported by them jointly and to render an impartial service to all roads alike. This latter plan, it is believed, would constitute an important initial step in any event, since such an organization should have no difficulty in attracting attention to the very valuable results to be derived from the work in which it would become engaged and thereupon should have no great difficulty in enlisting governmental or other outside support.

At the conclusion of Mr. Smith's remarks, Dr. W. F. M. Goss, whose presence had been anticipated during the discussion of the technical subjects earlier in the evening, was introduced, but owing to the lateness of the hour, he made only a few remarks.

This account is abstracted from the report given in the *Railway Review*, January 16, 1915.

ST. LOUIS, JANUARY 11

The Annual Meeting and Dinner of the St. Louis Section were held on the evening of January 16 at which Chairman Bausch acted as toastmaster. The speakers were Edward Flad, Consulting Engineer and Member of the Board of Freeholders; E. R. Kinsey, President of the Board of Public Service; Joseph A. Hook, Director of Public Utilities, Board of Public Service and E. R. Fish, Secretary of the Heine Safety Boiler Company.

Mr. Flad told of the framing of the New Charter for the City of St. Louis and particularly of the things in it of interest to engineers, dwelling especially on the board of efficiency, the introduction of the merit system in the hiring of city employees, and the concentration of power and responsibility in a board of public service consisting of five members, the president, and two members who must be engineers or at least ten years' experience.

Mr. Kinsey told of the scope of the duties of the Board of Public Service and how splendidly the provisions of the New Charter in regard to this board were working out. Under the New Charter, there has been an entire reorganization and separation of the departments each being placed under the supervision of specialists.

Mr. Hook spoke of some of the problems of his department, particularly that of the Free Bridge and the River Terminals, and asked the coöperation of the members. Suggestions were offered by Messrs. Boughton, Hibbard, Hunter, Kinsey, Salz, Flad, Nordmeyer and Wadleigh.

Messrs. Wadleigh, Seubert and Hunter gave brief reports of the St. Paul-Minneapolis meeting and Mr. Fish gave a report of the Annual Meeting.

NEW YORK, JANUARY 15

The New York meeting for January was held on the 15th of the month instead of the usual second Tuesday. A lecture was given by T. Kennard Thomson, D.Sc., consulting engineer, on A Really Greater New York. The lecture dealt in the main with the mechanical problems connected with the building of foundations for tall buildings and bridges particularly where caissons are required. Dr. Thomson showed many views of the foundation work in New York City, both past and present, of some of the best known buildings and explained in detail the many problems connected with the use of compressed air in caissons especially where as is the case in Manhattan, foundations must be carried to a great depth. The subject matter of the lecture naturally led to a discussion in conclusion of the possibility of a greater New York acquired through the construction of new land extending into the harbor and the East River with new transportation channels. This means that a greater increase of shore front could be secured to accommodate greater ocean traffic together with the facilities for handling freight including warehouses and other buildings.

PHILADELPHIA, JANUARY 14

A joint meeting of the Philadelphia Section with the Metallurgical Section of the Franklin Institute was held on January 14 with Prof. H. E. Ehlers and Prof. A. E. Outerbridge jointly presiding. Robert R. Abbott, Metallurgical Engineer for the Peerless Motor Car Company, presented a paper on Modern Steels and Their Heat Treatment. After considering the mixtures and compounds of iron and carbon present in steels, the proportions of these contained in steels of different carbon contents and their influence upon the strength of the material as indicated by percentage reduction in area in tension, the speaker described the effect upon the iron-carbon constituents produced by alloying with iron other elements such as nickel, chromium, manganese, etc. He then compared with this latter, the effects produced by heat treatment, showing that such effects were practically the same as those produced by alloying. He concluded with an outline of the commercial applications of heat-treated steel. The speaker illustrated his remarks by means of lantern slides of photo-micrographs and charts.

The paper was discussed by Prof. A. E. Outerbridge, Prof. Edgar Marburg, G. R. Henderson, H. V. Wille, Dr. Carl Hering, H. A. F. Campbell, E. W. Finkbner, J. T. Fennell, and others.

CINCINNATI, JANUARY 21

A joint meeting with the Engineers' Club of Cincinnati was held on January 21. R. W. Row of the Department of Public Service of Cincinnati spoke on the Engineering Features of the Proposed Rapid Transit System. About 100 members and guests were present.

NEUROLOGY

HERBERT NICHOLAS FENNER

Herbert Nicholas Fenner was born in Providence, R. I. on March 13, 1843. He obtained his early education in that city and after a few years experience in business, he succeeded his father in the New England Butt Company. He served as treasurer of that company for many years and at the time of his death was president. He was also a Director in the Industrial Trust Company and the Joslin Manufacturing Company.

Mr. Fenner took a great interest in public affairs, but never held political office. He was prominent in club life and was a director of the Puritan Life Insurance Company.

He died in Providence, R. I., on January 5.

HERBERT SELBY HAYWOOD

Herbert Selby Haywood was born at Brooklyn, N. Y., on September 19, 1845. His parents moved to Elizabeth, N. J. in 1852 and he was educated at Rev. David H. Pierson's school in that city. In 1862, he entered the Novelty Iron Works in New York City and served a four years apprenticeship in marine construction work and engineering. In July 1866, he entered the service of the Pacific Mail Steamship Company and made a voyage on the Steamship "Montana" through the Strait of Magellan to San Francisco. On several other long trips during the years 1866 to 1872, he filled positions as 2nd and 1st assistant and acting chief engineer. For about four years, he was detailed to service on branch lines on a steamer plying between ports in Japan, China and the Siberian Coast.

In April, 1873, he entered the service of the Pennsylvania Railroad Company as machinist in the Altoona shops. In 1874 he was detailed for special duty on the United Railroads of N. J. division as Assistant Road Foreman of Engines. He was appointed Assistant Superintendent of Motive Power in 1875 to which the marine department was added in 1881. In 1882, he was appointed Superintendent of Motive Power of this same division and also of the United Railroads of N. J. Division in 1883 and of the Camden and Atlantic R. R. including the ferries and floating equipment on the Delaware River in 1884. He had supervision of the motive power and marine equipment of the New York, Philadelphia and Norfolk Railroad from January 1, 1890 until his death.

During the 80's, he took out several patents, including an interior check valve on a locomotive boiler, one for a ear journal box and another, a cut off valve for a beam engine. This cut off valve was adopted by practically all of the ferries in New York harbor.

Mr. Haywood was one of the oldest members of the Society having become a member in 1880. He was also a member of the Society of Naval Architects and Marine Engineers, the Engineers' Club of New York, the Engineers' Club of Philadelphia and the New York Railroad Club. He died December 14, 1914.

CHARLES A. MOORE

Charles A. Moore, President of Manning, Maxwell and Moore, Inc., New York, was born at Sparta, N. Y. nearly 70 years ago. When he was 12 years old, he went to Lynn, Mass. to live with an uncle and receive his education. In 1862, he enlisted in the United States Navy and served until the end of the Civil War.

Fifteen years of his early business life were spent in and about Boston. During this time, he was connected with the Ashcroft Manufacturing Company and the Consolidated Safety Valve Company in the manufacture of steam specialties.

Mr. Moore later came to New York to be with H. S. Manning & Co. In 1881, the firm name was changed to Manning, Maxwell and Moore. At Mr. Maxwell's death in 1895, the business was left in the hands of Messrs. Manning and Moore. Mr. Manning retired in 1905.

In his busy years, Mr. Moore was very active in Republican politics. He was President of the American Protective Tariff League, and one of the founders and for ten years president of the Montauk Club in Brooklyn, N. Y., a member of the New York Chamber of Commerce, and the National Association of Manufacturers and several other societies and clubs. Mr. Moore died on December 8, 1914.

FRANK RUSSELL PACKHAM

Frank Russell Packham was born at Hadley, Michigan on May 11, 1855. He received his early education in Canada and his first business training with his father who was a miller. He also served an apprenticeship in a sewing machine factory and learned the machine and pattern making trades.

When he was 18 years old, his parents moved to Springfield, Ohio, where Mr. Packham was employed as a machinist for the Wardell-Mitchell Company which is now a part of the International Harvester Company.

In 1878, he became superintendent and experimental man

for the Baker Drill Company in Mechanicsburg, Ohio, and manager and designer of turner's tools for the Packham Crimper Co. until 1886.

In 1887, he returned to Springfield and identified himself with the Superior Drill Company devoting his time to designing and pattern making.

Upon the formation of the American Seeding Machine Company, Mr. Packham was made a director of the company and manager of the experimental department. This position, he held until the time of his death.

As an inventor, Mr. Packham contributed as many as 150 improvements on various agricultural implements, most of which are now manufactured by the American Seeding Machine Company. Probably his most important work was the invention and development of the "single disc" drill.

In 1900, Mr. Packham was appointed by Secretary Wilson as a representative of the United States Government to tour the world in the interests of the Foreign and Domestic Bureau of Commerce. In 1909, he was appointed mechanical guide to the Honorable Commercial Commission of Japan in its visit to this country.

Mr. Packham died at Springfield, Ohio, on January 1.

WILLIAM R. ECKART

William R. Eckart was born in Chillicothe, Ohio, June 17, 1841. His relatives were pioneers in the settlement of that part of the State, but in 1842 his family moved to Cleveland, where his father had large shipping interests on the Great Lakes. His early education began in private schools, but from the time he was twelve years old his school days were divided between the public schools of Chillicothe and Cleveland. Later, he took a special course in mathematics at the St. Clair Street Academy, Cleveland, with the view of becoming a civil engineer.

In the early fifties his father removed to Zanesville to engage in the operation of a flour mill, operated by water power, and after the installation of some improved water wheels, Mr. Eckart received the opportunity to serve an apprenticeship in the works of Griffith, Ebert and Wedge, which in those days, had a high reputation for general mill and steamboat work; this was a welcome opportunity as the fascination of steamboat work had taken hold of his ambition while traveling on the Ohio and Mississippi rivers. In his apprenticeship he was fortunate in having the friendship and guidance of Mr. Wedge, who found the time to show him how to improve upon his work after he had thought it "good enough."

Mr. Eckart's river experience aroused a desire for naval life, and in June, 1861, he took an examination before the Board of Engineers. On July 30, when he was twenty years of age, he was appointed Third Assistant Engineer in the navy and was ordered at once to join the fleet of naval vessels on the Pacific coast. On July 10, 1864, Mr. Eckart resigned from the navy on account of ill health and took up his residence in San Francisco, where he began work in the drawing room of H. J. Booth and Company. While with this company, he made the designs and drawings for the first California built locomotive. He remained with this company until February, 1869, when he received an appointment as draftsman in the Steam Engineering Department at Mare Island Navy Yard. He was afterwards made foreman machinist and later was promoted to superintendent of steam machinery through B. F. Isherwood's recommendation.

In 1871 Mr. Eckart left the Navy Yard to enter into partnership with Prescott, Scheidel and Company, at the Marysville Foundry. The firm name was later changed to Booth and Eckart. It was while there that Mr. Eckart contracted for, designed and built the steamer Meteor for the Carson Lumber Company, with a guaranteed speed of 21 miles per hour; this steamer was used on Lake Tahoe and was probably the fastest boat of her size known at that date.

In 1876 Mr. Eckart was recalled by the Prescott, Scott and Company, who were the successors to H. J. Booth and Company, to superintend the construction and assist in designing and erecting some pumping machinery for the Comstock Lode. About this time he moved to Virginia City to become consulting engineer to the "Bonanza Firm" that owned or controlled nearly all of the "North End" Mines. During this time he was manager of the Fulton Foundry, Virginia City. In 1878 he was appointed U. S. Deputy Mineral Surveyor for the State of Nevada. While still a resident at Virginia City he designed and built, in connection with W. J. Sakeld, a noted millwright at that time, the Bulwer Standard Mill, at Bodie, which was one of the largest pan mills for working ore that had been built at that time.

During the early part of 1880, Mr. Eckart was appointed a member of the U. S. Geological Survey under Clarence King and was given charge of investigating and reporting upon the mechanical appliances of the Comstock Lode. On this work, which was really a labor of love, he spent nearly two years collecting data, testing pumps, engines and hoists, and making drawings for the Government of all the machinery on the Comstock. The finest instruments procurable in the United States and Europe were used in the various investigations of efficiency.

In 1881, Mr. Eckart removed to San Francisco and opened offices there as a consulting and constructing engineer, and during the following eight or ten years some of the largest and most important mining plants were designed and constructed under his supervision. The pumping engine for the Ontario Mine, with perhaps the largest Cornish pumps for deep mining ever built in the United States, were constructed from his designs during this period. In 1881, he began for Haggin and Tevis, plans for all of the Anaconda Works, hoists and reduction works, and during the next seven years, all their mining work and mills were designed by him.

In 1883, The Union Iron Works, formerly Prescott, Scott and Company, was changed to an incorporated company and Mr. Eckart was retained as consulting engineer in matters pertaining to the propelling power of the Government vessels built by that company. He was present at and assisted in conducting nearly all the preliminary and government trials of these vessels.

In 1899, he was appointed consulting engineer to the Standard Electric Company and afterward became the resident construction engineer for all their hydraulic works, including storage, reservoir, ditches, dams, flumes, pipe lines and power house installations. This was the first or among the first of the long distance, high-potential-transmission, hydraulic plants projected.

Mr. Eckart was a member of the American Society of Civil Engineers, The Institution of Mechanical Engineers, The Society of Naval Architects and Marine Engineers and an Associate Member of the Institute of Naval Architects. He was Vice-President of this Society from 1883 to 1886.

Mr. Eckart died at the home of his son, in Palo Alto, Cal.,

on December 8, 1914, after a very successful engineering career covering a period of fifty years' practice on the Pacific coast, which, as he once said, was due "to a studious life surrounded by an extensive collected engineering library of American and foreign books and the appreciative assistance of associated engineers, together with the encouragement and loyalty of employers."

PERSONALS

Louis H. Mesker has accepted a position with the sales department of the Kearney & Trecker Company, Milwaukee, Wis. He was until recently connected with the Anderson Forge and Machine Company, Detroit, Mich.

Henrik Greger, recently associated with the Epping Carpenter Pump Company, Pittsburgh, Pa., as assistant chief engineer, has become affiliated with The Prescott Company, Menominee, Mich., as mechanical engineer.

Alfred W. Charles has accepted the position of chief draftsman with the Canadian Copper Company, Copper Cliff, Ont., Canada. He was formerly connected with the Anaconda Copper Mining Company, Butte, Mont., in the same capacity.

Russell B. Bedford until recently President of the Railway Material Export Corporation, New York, has assumed the position of export manager and manager of the Eastern branch of the Chicago Foundry and Manufacturing Company, Kalamazoo, Mich., with headquarters in New York. He is also engaged in personal consulting engineering work.

Arthur G. McKee has lately formed a corporation with his two business associates, Robert E. Baker and Donald F. Herr under the name of Arthur G. McKee and Company.

Henry Souther, Chairman of the Standards Committee of the Society of Automobile Engineers, has been made a life member of that Society in recognition of his distinguished achievement in the orderly development of the art of automobile engineering. At the Annual Meeting of that Society, Mr. Souther was presented by his associates with a silver piece suitably engraved, as a token of the admiration and affection in which he is held.

H. C. Spaulding has severed his connection with the Society for Electrical Development and is now connected with the Frank Presbrey Company organizing their electrical service department.

Edward M. Hagar was appointed Honorary Vice President to represent the Society at the American Road Builders' Association in Chicago at its Eleventh Annual Convention, December 14-18, 1914. This convention was held in conjunction with the Sixth Good Roads Show. The commercial exhibits included samples used in road construction and maintenance, such as stone, gravel, asphalt, tars and brick, together with exhibits illustrating the various exhibits employed in the testing of road material; sections of patented pavements and pavements built with patented materials; construction equipment varying from tools to heavy machines; models of contractor's equipment, engineering and testing instruments.

In the arena of the amphitheatre in which the show was held an oval boulevard was laid out surrounding a park which was set with trees, and contained a gravel walk and a fountain. The boulevard proper was constructed of various types of paving materials, such as asphalt, macadam, brick, wood blocks, concrete, tar, macadam, and asphaltic concrete. The exhibits bordering the parkway were those of the Bureau of Streets of the cities of Chicago, New York, Philadelphia and Boston, and of the State Highway Commissions of Illinois, Michigan, Iowa, Arizona, Washington, Kansas, Kentucky, New York, Virginia, Rhode Island and

Maine and of the North Carolina Geological and Economic Survey. In addition, the United States Government was represented by a very interesting exhibit from the office of Public Roads of the Department of Agriculture, and Canada, by an exhibit from the Highway Commission of Ontario.

STUDENT BRANCHES

CARNEGIE INSTITUTE OF TECHNOLOGY

At a meeting of the Carnegie Institute of Technology Student Branch on January 13, E. H. Bickley, C.I.T. '09 read a paper on some of the things he had learned and done since he left Carnegie Institute, and made the following suggestions to the students: know your materials; learn from the practical man; everything we do, think or say has a cost; what you cannot produce quickly is not your own; what you can produce quickly is what you are valued at.

Mr. Bickley then told of some of his work at the H. J. Heinz plant at Pittsburgh. He cited a number of instances to show how wastes had been eliminated and explained his system of card indexes and curves which he used in keeping track of the various operations going on in the plant. For instance, in a department where water or compressed air is being used, meters are put in the line. A report is received from the foreman of the department and this is plotted on the curve. A rise in the curve immediately denotes that there is something wrong.

The speaker then described his invention, the motorgraph which is an electrical sign on which the letter forming words appear at the right side of the sign and move across the face, disappearing on the left side. The lettering and motion is controlled by a moving perforated strip of paper and because of this simple control, changes in the lettering can be made almost instantly, and a continuous stream of different reading matter can be flashed across the sign.

COLORADO AGRICULTURAL COLLEGE

At a meeting of the Colorado Agricultural College Student Branch on November 19, the following officers were elected; A. T. Johnson, chairman; W. K. Morrison, vice-chairman; and T. H. Sackett, secretary-treasurer. A programme committee was appointed consisting of the chairman, vice-chairman and the secretary.

At a meeting on November 23, the progress of Oxy-Acetylene Welding was reviewed by E. S. Murray and Standardizing Machinery was discussed by W. K. Morrison.

On December 7, Recent Developments in the Diesel Engine, by H. R. Setz was discussed.

At a meeting held on January 4, Prof. Albert Cammack gave an extemporaneous talk on Tool Steels. He outlined briefly the history of the development of tool steel, speaking particularly upon the tests, use and manufacture of modern high speed steels. He discussed hardening and tempering steels and the economy resulting in the employment of the high speed steels.

KANSAS STATE AGRICULTURAL COLLEGE

At a meeting of the Kansas State Agricultural College Student Branch on January 14, Prof. S. L. Simmering of the mechanical engineering department gave a paper on Manufacturing Wire Nails. From the ore as taken from the mine, Mr. Simmering told of its progress through the plant until it comes out a finished product. When the ore is first received, it is run through the crusher and a sample for chemical analysis is taken from each lot and from this, the amount of impurities is determined. In making up a charge for the blast furnace, the ores are mixed in proportions so that the resulting iron will be within the allowable limit of impurities. The iron is taken from the blast furnace to the Bessemer converters and made into steel, which steel is cast into ingots and then rolled to a square about four by four in. and cut into twenty-four inch lengths. These blocks are then heated and rolled to a three-eighths in. rod. This rod from the rolling mill is coiled in bundles the same as wire, heated and annealed in lime. It is then

cold drawn to the size required for the nail. One machine makes the complete nail.

KANSAS UNIVERSITY

At the regular meeting of the Kansas University Student Branch, on January 7, S. E. Campbell discussed an article on Cost Accounting by William Keet which appeared in Industrial Engineering. He spoke principally upon its economic value in large plants rather than upon methods of keeping cost accounts.

Dean P. F. Walker, Honorary Chairman of the branch, spoke briefly on the Annual Meeting at New York. He gave a general outline of the whole meeting, explaining how it was conducted and touched slightly upon some of the papers given.

At a meeting on January 14, Dean Walker continued his talk and spoke of the purpose and value of engineering societies of all branches to the engineering profession. Although he spoke more specifically of the Am. Soc. M. E., he gave briefly the histories of many other important engineering societies such as the American Society of Civil Engineers and the American Institute of Electrical Engineers.

LEHIGH UNIVERSITY

Prof. Thomas E. Butterfield and a party of Seniors from Lehigh University visited New York during the week January 4-9 on their annual tour of inspection of large engineering plants. A visit was made to the Engineering Societies Building, where the students were shown the Library with its wealth of engineering and scientific literature, the headquarters of the Mining, Electrical and Mechanical Engineering societies and the Museum of Safety, where there is a permanent exhibit of all types of safety appliances.

All students who intend to live in New York upon graduation are invited to make the Society their headquarters and avail themselves of the Library and other privileges.

STEVENS INSTITUTE OF TECHNOLOGY

The Student Branch at Stevens Institute of Technology held its second lecture on December 15. J. I. Lyle, General Manager of the Carrier Air Conditioning Company gave a very interesting talk on Air Conditioning, giving examples of many of the applications of drying and humidifying air in the industries. The talk was appreciated because it dealt with subjects with which all of the hearers were conversant and because it was treated clearly and concisely. Views of air conditioning apparatus as used in its applications, were used as illustrations.

Another lecture was held on January 5. The speakers were L. E. Moulthrop, superintendent of construction for the Boston Edison Company and J. W. Parker, assistant superintendent of operation of the same company. Mr. Moulthrop gave a brief outline of the history of the company, describing its original equipment contrasting it with that of the present plant. He also enumerated the various items to be considered in choosing a site for a power plant. Mr. Parker told how the responsibility for each part of the work was divided among the men, and how the welfare of the workmen was taken care of. He also described the company's method of handling their peak load. Both speakers illustrated their talks with lantern slides.

UNIVERSITY OF CINCINNATI

At a meeting of the University of Cincinnati Student Branch on January 15, B. S. Hughes of Steigener, Hughes and Alvez, Consulting engineers, gave a lecture on The Problems of a Consulting Engineer. As an illustration of the conditions which may confront the consulting engineer, Mr. Hughes assumed that he was to build a power plant with a certain capacity and that the expense item was no object. For a plant which would be operated under these conditions, under a scientific management, and with a skillful staff, it would be advisable to install a high grade system of units, and probably include all of the modern heat-saving appliances. If, however, the plant was not to be

operated under scientific management, it would be advisable to install units of lower initial cost.

Mr. Hughes cited several examples which illustrated the various conditions affecting the design and operation of power plants. He mentioned the equipment of steam power plants with condensing units, where live steam was used for drying purposes in the factory which was an obvious waste of funds for initial cost and operation. Another case in which an important item was overlooked was that of the large paper mills in the South which were splendidly designed from an engineering standpoint, but which were surrounded by such unattractive local conditions that good men could not be induced to stay.

At the close of the paper, Prof. A. L. Jenkins, of the University of Cincinnati, and others informally discussed the paper.

UNIVERSITY OF COLORADO

At a meeting of the University of Colorado Student Branch on January 14, R. N. Robertson, mechanical engineer of the American Smelting and Refining Company, spoke on Boiler Setting and the Altitude Effect. Mr. Robertson discussed rather fully the matter of boiler settings for different coals used at various altitudes. He brought out the principle points in connection with combustion under these conditions, giving the qualities of various coals and their relation to the design of furnaces. The speaker said that the altitude is a very important factor in combustion. About 50 per cent increase must be made in the fires and combustion chamber and 75 per cent increase in the height of the stack to cause the proper draft for complete combustion with the rarified air at altitudes of two miles or more.

Mr. Robertson showed some new designs of settings and results from his own experience with soft coals in the company furnace, and some new points on combustion. The speaker believes that the under-feed is the best form of stoker for all purposes and all conditions and that there is no doubt that it is coming to be the prevailing form.

UNIVERSITY OF MISSOURI

The University of Missouri Student Branch held a meeting on December 17, at which Stanley Goodman and P. R. A. Nolting read and discussed their paper on The Effect of Various Constituents of Coal upon the Fusing Point of its Ash.

At a meeting on January 10, F. N. Westcott read a descriptive paper on the St. Louis Water Works System, and F. P. Hutchinson read a paper on Smoke Prevention.

EMPLOYMENT BULLETIN

Note: In sending applications stamps should be enclosed for forwarding.

The Secretary considers it a special obligation and pleasant duty to be the medium of securing positions for members, and is pleased to receive requests both for positions and for men. The published notices of "men available" are made up from members of the Society. Notices are not repeated except upon special request. Names and records are kept on the office list three months, and if desired must be renewed at the end of such period. Copy for the Bulletin must be in hand before the 12th of the month.

POSITIONS AVAILABLE

010 Mechanical engineer as assistant superintendent for cement mill, New York State. Applicant should have a technical education as well as practical experience, and must have demonstrated his ability to handle men efficiently. One who has had cement mill experience preferred, and competent and willing to make a study of the repair costs. Salary \$150.00 per month. Apply through Society.

011 Man capable of superintending power and plant and assisting production superintendent in large cement manufactory. Salary rate \$150.00 per month. Location New England.

013 Assistant superintendent for chemical manufacturing plant in Middle West employing 1500 men. Chemical

education and experience in handling men and machinery required; applicant please state age, education, previous experience, salary received heretofore and salary desired.

014 Mechanical engineer with good designing ability and large experience in conveying machinery to take charge of drafting and engineering department of company manufacturing conveying machinery. Give experience, references, salary expected and full particulars which will be treated strictly confidentially. Location Middle West.

015 Chief draftsman, man experienced in the design and manufacture of sheet metal products such as office furniture, filing cases, and similar equipment, competent to systematize and direct the work of thirty to forty men. Give age, education, experience, references, and the salary expected. New York concern.

019 Laboratory instructor. Salary beginning at \$1500 per year with excellent opportunity for promotion. Location Nevada.

020 Resident engineer on construction and extension of cement plant in Tennessee. Salary between \$150 and \$200 per month. Apply through Society.

021 Good designing draftsman, experienced in designing automatic paper forming machinery such as envelope or paper box machinery, and one who has had several years of machine shop training. Location New York.

022 District representative wanted in one of the large Middle West cities to handle steam turbine account. Applicant must have had experience in steam engineering practice and the application of turbines, turbo-pump sets, turbo-generator sets and turbo-blower sets, and the sales ability necessary to the successful handling of the account. Apply through the Society.

023 Foundry and machine shop located in Metropolitan district wishes services of technical man with about ten to twenty thousand dollars to invest. Apply through Society.

024 Young man for work in efficiency department of middle west concern, with shop experience and possibly some experience in efficiency work. Will require a man with initiative. Applicants state in detail experience and give the approximate salary that would be considered. Names of former employers should be included.

025 General foreman of large machine shop manufacturing large generators and other work of a kindred character. Apply through Society.

026 Wanted party with capital to assist in financing the development of important improvements in the design and application of hydro-pneumatic apparatus.

029 An engineer of established reputation on the Pacific Coast desires partner with capital to form a corporation to engage in general engineering and contracting business. One who has had previous experience or technical knowledge and ability to get business. New York interview desired.

030 Agency wanted for small patented electrical device of foreign invention. Apply by number.

031 First-class designer in concern in New York State making paper printing, and book machinery, etc.

032 Large manufacturing company with modern steel working equipment and complete organization, has capacity larger than at present required. Will be pleased to hear from parties desiring the manufacture of their products. Apply through Society.

033 High grade shipping clerk to take charge of the output of a firm employing 750 men at the present time working night and day. Would consider only man thoroughly experienced. Location Connecticut.

036 Man to take charge of a foundry, machine shop and blacksmith shop now in course of erection; not necessary that he be a craftsman, but rather a good handler of men and with a knowledge of cost accounts, etc. Establishment is for repair work for large iron mines. Apply by number.

MEN AVAILABLE

B-1 Junior, graduate M.I.T., mechanical engineer, age 30, married, five and one half years experience in design and construction of power plants and illumination of textile mills, sales of electro power, and preparation of contracts, desires position in engineer's office as assistant to manager, superintendent of a cotton mill, master mechanic or purchasing agent.

B-2 Junior, technical graduate in mechanical and electrical engineering, ten years experience in design, construction, operation and maintenance of power house and substations, high voltage electric design, piping design and layouts, etc., and building designs, desires position as power engineer, assistant superintendent of large mill, or designing engineer for large engineering firm or contractor.

B-3 Mechanical engineer, five years experience in design and reproduction of agricultural and marine gas and oil engines, one year in charge of mechanical and of a new food product, desires responsible position in production or sales department.

B-4 Member, 12 years experience in designing, as superintendent of construction, as transit man, in transmission, purchasing, shipments and office details, as operating superintendent of 3000 barrel cement plant, connected with plants in the East, Middle West and Central South, desires to connect with responsible firm. Location immaterial.

B-5 Mechanical engineer, well qualified by technical education, experienced in research along lines of engineering physics, desires position involving industrial research or experimental engineering. Would also consider position as salesman on the road.

B-6 Member, graduate mechanical engineer, age 34, 11 years successful experience in designing, manufacturing, experimental and sales engineering; gas and oil engines of small and medium sizes, gas and electric hoists and draw bridge machinery, gas and oil tractors, railroad water service, coal and ore unloading dredge machinery. Well qualified for position as chief draftsman, experimental or production engineer or assistant superintendent. Practical and resourceful in economic methods of manufacture.

B-7 Member with well established office in New York desires to correspond with responsible concerns in regard to representation.

B-8 Associate member, graduate M.E., 1910, age 33, three years experience teaching and two of practical experience, has ability to superintend and increase efficiency of production. At present employed as assistant superintendent of small factory, desires position along similar lines, or will consider other opportunities in mechanical engineering; would also accept teaching position.

B-9 Member, technical graduate, 15 years experience supervising design and construction of power plants, office and factory buildings, mechanical equipment and fire protection systems, drawing specifications and contracts, desires position along similar lines, or with consulting engineer. At present employed by large industrial corporation in administrative engineering capacity.

B-10 Member, 25 years experience in mechanical, electrical and automobile work, thoroughly up-to-date in economical manufacture and time saving methods, desires position as manager, mechanical engineer or salesman.

B-11 Mechanical engineer, technical graduate, age 30, thorough knowledge of all types of pumps and pumping machinery, gasoline and oil engines, sugar house machinery,

drawing room, erection room, and engineering department, desires responsible position, sugar plantation work in Mexico or sales engineer in Brazil.

B-12 Member, 30 years experience in hydraulic forging machinery and other heavy machines for the manipulation of metal, desires position as designing adviser or executive along these lines. Can be engaged for part time if desirable.

B-13 Member, age 34, technical graduate, 11 years experience in mill engineering and central station work consisting of designing, drawing up specifications, buying equipment, supervising installation, managing operation and maintenance, good executive and accustomed to handling high grade men, desires position as works engineer or with consulting engineer. At present employed.

B-14 Engineer with ten years experience in building up sales organizations, factory improvements in paper mills, tanneries, chemical works, metal working plants, machine tool building, clothing industries, etc., and having established large consulting practice in management engineering for a firm of industrial advisers, desires position with similar engineering or accounting firm.

B-15 Electrical and mechanical engineer, graduate University of Illinois, 1901, post graduate, 1910-1911, E.E. and M.S., 13 years practical experience in testing, design, construction, operation and management of steam, electric and hydro-electric plants, including generation, high-tension transmission, distribution of electric light and power for mines and cities in the United States and abroad, investigations and reports, is open for immediate engagement. Location immaterial.

B-16 Member, Stevens graduate, 25 years experience, well established record with prominent concerns, engaged in interchangeable manufacture, especially apt on tool design for large production with high degree of accuracy, successful executive in engineering and productive lines, desires position as manager, superintendent or mechanical engineer.

B-17 Graduate M.I.T. in mechanical engineering, two years experience in maintenance of power equipment, plant and designing new factory building with large manufacturing concern, two years inspecting reinforced concrete and steel structures with irrigation project, familiar with reinforced concrete design, desires position with construction firm, or power and plant department of manufacturing concern.

B-18 Cornell graduate, age 33, one and one-half years study of railroads in Germany, eight years railroad shop experience, desires position with engineering or manufacturing firm, or shop machine tool works. At present employed as practical instructor of apprentices.

B-19 Cornell graduate, age 28, married, seven years experience as machinist, toolmaker, master mechanic and chief engineer in charge of power and refrigeration plant, desires position in experimental work, testing, design or teaching mechanical engineering subjects.

B-20 Mechanical engineer, student member, 1914 graduate of large Eastern university, desires position with industrial or commercial concern.

B-21 Junior member, M.I.T. graduate, age 27, married, four and one half years experience, including drafting, power plant, textile machinery, office and executive work, desires permanent position with reliable concern offering chance for advancement.

B-22 Student member, graduate of University of Missouri, desires engineering position of any kind which offers chance for advancement.

B-23 M.I.T. graduate in mechanical engineering, nine years experience in motive power department of a large railway system, desires position with railway company in either M. P. or C. T. department. Location immaterial.

B-24 Associate-member, graduate M.I.T., associate A.I.E.E., age 26, experienced in teaching and as foreman, assistant superintendent and experimenter, desires position with manufacturer or experimenter.

B-25 Graduate engineer with ten years practical experience in power, heating and refrigerating work, including installation, design and estimating, would like to have the opportunity of doing some work while confined to his home. Has had special experience in physics, chemistry and calculus and would be willing to do editorial work in these and in engineering subjects.

B-26 Member, graduate of M.I.T., with broad experience, would like executive position, or position as assistant to chief executive in large concern. At present employed but desires change.

B-27 Mechanical and electrical engineer, graduate W.P.L., age 26, experienced in machine shop and steel mill work desires to make change. At present employed.

B-28 Superintendent or factory manager familiar with most modern practice in machine shops, foundries and manufacturing plants, competent to design tools and fixtures for increasing production and reducing costs.

B-29 Mechanical engineer, age 31, 14 years experience, desires position in engineering, sales or drafting department. Detail of education and experience furnished to those interested.

B-30 Mechanical engineer, technical graduate, age 38, 13 years experience in manufacturing lines, shop, operating, drafting, engineering, efficiency, sales including railroad. Corliss engines, gas engines and producers, saw mill, mining machinery, transmission and special machinery, complete steam and gas power plants.

B-31 Junior, mechanical engineer, Columbia graduate with varied experience desires to connect with an industrial concern, not necessarily in an engineering capacity at the start. Location immaterial.

B-32 Engineer, Stevens graduate, age 31, unmarried, capable manager, excellent designer, experienced writer of specifications, has just completed supervision of several large manufacturing plants, desires position as chief engineer for firm of industrial engineers and architects. Especially with South, location immaterial.

B-33 Member, long and valuable experience in responsible positions in design and construction, supervision of printers' machinery, thorough knowledge of field and requirements and construction of rotary web presses, folders, flat beds, offsets, electrotypes and stereotype machinery. Employed as chief draftsman.

B-34 Member, technical graduate, age 34, married, 16 years experience, including wide shop drafting room and outside experience, mainly in automobile and motor truck lines. Capable of handling advertising and publicity and engineering department at the same time as shop details and executive correspondence. Location preferred vicinity of New York.

B-35 Member, technical training, age 35, married, 14 years experience with large industrial concerns in many capacities up to superintendent is open for a position requiring the services of an engineer executive whose predominant ability is along mechanical lines and who is capable of assuming charge of the operation of the works of a large department. At present employed.

B-36 Junior member, technical training, 11 years experience, including foundry and machine shop practice, design, reorganization, construction, equipment of mill buildings and power plants, estimates, schedules of materials, building specifications and appraisals, fire service piping, sewage disposal and surveying, also as assistant on steam engine tur-

bine and boiler tests, desires to locate permanently as mechanical engineer, assistant to engineer or works manager.

B-37 Member, sales engineer, established in New York, with a broad acquaintance in New England and Middle Atlantic States, desires to secure an additional account, preferring plant equipment or steam specialty. Salary or commission.

B-38 Member, technical graduate, 15 years shop and drafting room experience designing and superintending construction; thoroughly trained in machine shop, pattern shop and foundry work, with exceptional ability in tool designing and inventive work, desires position as instructor of machine design or with consulting engineer or manufacturer where there is opportunity for advancement. Location preferred, Eastern or Central States.

B-39 Student member, age 26, technical graduate M.E., experienced as machinist, mechanical draftsman, desires position as assistant to engineer, superintendent or manager of engineering concern. Location immaterial.

B-40 Contracting engineer, college graduate, age 40, eight years experience as contractor for steel works, furnaces and structures, desires connection with steel company or firm of contractors.

B-41 Junior member, age 28, graduate mechanical engineer, five years practical experience, last two and one half years engineer of tests of large automobile company, desires position as assistant superintendent or engineer.

B-42 Mechanical engineer thoroughly familiar with design and operation of power plants, railroad electrical engineering, shops, etc., desires position.

B-43 Graduate mechanical and electrical engineer, experienced in design and construction of machinery, building, manufacturing, systematizing, accounting, refrigeration, desires permanent position in New York.

B-44 Mechanical engineer and superintendent, 12 years experience, in present position four years. Qualified to accept position as assistant general manager, superintendent, or mechanical engineer. Now employed but would resign to accept advantageous offer.

ACCESSIONS TO THE LIBRARY

This list includes only accessions to the library of this Society. Lists of accessions to the libraries of the A. I. E. E. and A. I. M. E. can be secured on request from Calvin W. Rice, Secretary of Am. Soc. M. E.

RAILWAYS AND PROSPERITY. Address by W. G. Harding, at the annual dinner of the Railway Business Association, December 10, 1914. Gift of Fairfax Harrison.

REINFORCED CONCRETE CONSTRUCTION, G. A. Hool. vols. 1-2. *New York, 1912*.

THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS

ABRIDGED LIST OF OFFICERS AND COMMITTEE CHAIRMEN¹

JOHN A. BRANSHEAR, *President*

CALVIN W. RICE, *Secretary*

Finance Committee, R. M. DIXON

House Committee, S. D. COLLETT

Library Committee (to be appointed)

Committee on Meetings, J. H. BARR

Committee on Membership, W. H. BOEHM

Publication Committee, C. I. EARLE

Public Relations Committee, M. L. COOKE

Research Committee, R. C. CARPENTER

Committee on Constitution and By-Laws, JESSE M. SMITH

LOCAL MEETINGS

Atlanta: Earl F. Scott

Boston: H. N. Dawes

Buffalo: David Bell

Chicago: S. G. Neiler

Cincinnati: J. B. Starwood

Los Angeles: Walter H. Adams

Milwaukee: L. E. Strothman

Minnesota: Wm. H. Kavanaugh

New Haven: H. B. Sargent

New York: Edward Van Winkle

Philadelphia: H. E. Ehlers

San Francisco: C. R. Weymouth

St. Louis: F. E. Bansch

¹ A complete list of the officers and committees of the Society will be found in the Year Book for 1915, and in the January and July 1915 issues of The Journal.

ROLLA C. CARPENTER

E. D. MEIER (Deceased)

CHAS. L. HUSTON

JOHN A. STEVENS, *Chairman*

EDWARD F. MILLER

WM. H. BOEHM

RICHARD HAMMOND

MEMBERS OF THE ORIGINAL BOILER CODE COMMITTEE, APPOINTED SEPTEMBER 15, 1911

COMING MEETINGS OF THE SOCIETY

March 9, New York City. Paper: The Application of Engineering Methods to the Problems of the Executive, the Director and Trustee, by Dr. Hollis Godfrey, president of Drexel Institute.

April 12, Philadelphia, Pa. Joint meeting with the American Institute of Electrical Engineers. Papers: Engine Driven vs. Turbine Driven Units in Small Capacities, by Albert C. Wood; and Washing and Cooling Air for Use with Electrical Apparatus, by an author to be announced.

April 21, New Haven, Conn. Spring meeting, with afternoon and evening sessions. Subject: The Development of Machine Tools.

April 23, Boston, Mass. Joint meeting under the auspices of the American Institute of Electrical Engineers.

March 11, Buffalo, N. Y. Subject: Interesting Features Involved in the Design of the Connors Creek Plant of the Edison Illuminating Co. of Detroit, by C. F. Hirschfeld of Detroit.

March 25, Buffalo, N. Y. First Member Speakers' Meeting. Papers: Present Status of Fuel Oil Engine in United States, by S. B. Daugherty of Snow Steam Pump Works; Conservation, by H. B. Alverson of Cataract Power and Conduit Co. (Niagara Falls Power Co.); and Power Equipment Used in Steel Plants, by E. E. Kiger of Lackawanna Steel Co.

April 2, Chicago, Ill. Subject: Power Plant Apparatus and General Equipment.

THE JOURNAL OF THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS

March 1915

Number 3

COMPLETION OF THE BOILER CODE

A SIGNAL event for the boiler industry and one that means much to the field of power production in general, was the completion of the report of the Committee to Formulate Standard Specifications for the Construction of Steam Boilers and Other Pressure Vessels and for Care of Same in Service, and its presentation to the Council of the Society on February 13, 1915. Its approval by the Council—the governing body of the Society—and the authorization granted for immediate printing of the report as a Boiler Construction Code marks a new era in the manufacture of steam boilers, and it is hoped, will prove the inauguration of a movement of considerable importance for the protection of human life and property. The benefits that will accrue from an economical standpoint, when the rules for construction embodied in the new Code are generally put into effect, are far-reaching, and will affect alike the manufacturer and the user of boilers.

The work involved in the final revision of the Code was one of the most strenuous and trying committee undertakings ever carried out in the history of the Society. As stated in the February issue of The Journal, the work of revision began on December 15, 1914, and was carried on continuously without interruption until February 3, 1915, covering a period of nearly eight weeks of the most exacting and painstaking work. The Boiler Code Committee worked constantly in conference with the Advisory Committee which had been appointed in December and the sessions, which were both investigative and judicial in character, were marked by a peculiarly intense interest of the committee members and the most unusual display of energy. The daily sessions lasted usually throughout the day and until midnight and the attendance was usually a majority which is a matter worthy of note when it is considered that the committee members came from all parts of the country and some of whom were in constant attendance for the entire seven weeks. A notable feature of the final revision was the amount of research work involved, several series of tests having

been carried out by members of the committee to check and establish the authenticity of the rules and formulae embodied in the Code.

The work of the Committee, as previously stated in The Journal, was confined to rules for construction of steam boilers only, all references to "other pressure vessels" and to laws and matters of legislation having been omitted. The result of the work of revision of the construction rules was the division into two parts, one for new installations and the other for existing installations, and following this was provided an appendix in which were placed the rules, examples, illustrations, references, and data that were in nature supplementary to the rules. As now laid out, the rules for existing installations (Part I) covers all details of construction of new steam boilers and the rules for allowable working pressures upon them, the details being referred to in the following order: Materials of construction, including the material specifications, maximum allowable working pressures, boiler joints, braced and stayed surfaces, combustion chambers, tubes, riveting and caulking, manholes and handholes, safety valves, water and steam gages, and fittings and appliances. At the end of Part I is a section devoted to heating boilers, in which the above order of subjects is also adhered to. In Part II which is devoted to existing installations, the same order of subjects is followed, although less complete and exacting in details.

The text of the Code in its revised form was printed in the form of printer's galley proof and sent to each member of the Council of the Society, as well as to each member of the Boiler Committee and the Advisory Committee for final proof-reading, on February 3, ten days before the Council meeting on February 13. At the Council meeting on this latter date at which the whole Boiler Committee was invited into conference, the report was approved by the Council in full, as finally revised, and was ordered to be printed as soon as possible for general distribution; and pamphlet copies are being issued as a preprint of the

Transactions of the Society. Following the approval of the report, action was taken by the Council commending the Boiler Committee and the Advisory Committee for the heroic work that it had carried out in such a painstaking and careful manner and expressing the gratitude and appreciation of the Society to the enlarged Committee for the great work it had done for mankind.

The next step taken by the Committee was a careful proof-reading of the entire report for typographical errors and the preparation of the Code for final printing. It is now being issued in pamphlet form as above mentioned, at \$1.00 per copy to members and \$1.50 to non-members. Later the Code will be distributed to the entire membership.

It is pleasing to note that the Code is finding immediate application. The State of Indiana is at this time considering the matter and it is very probable that an amendment will be passed by the legislature rendering the former Indiana boiler code optional, with the proviso that the A.S.M.E. Code may be used for boiler construction in place of the present State code if desired. The Ohio State Boiler Board has the new Code under consideration and it is possible that it will be adopted in place of the boiler code now in force in that state. In Wisconsin the Code will probably take immediate effect as a result of an action of the Industrial Commission of Wisconsin taken last year looking forward to the A.S.M.E. Code before it was completed; while a preliminary set of boiler rules was put into effect in that state the first of this year, provision was made for their replacement by the A.S.M.E. Code as soon as finished.

With the completion of this great work, considerable interest attaches to the originators of the movement, the committee of seven members, appointed in 1911. The choice of these members represents the exceptional wisdom and foresight of the officials of the Society in their concern that all the various branches of the industry should be represented. John A. Stevens, a consulting engineer of extended power plant experience who was appointed chairman, offered the advantages of his experience in formulating the Massachusetts code, the first state boiler code that was put into effect in this country. R. C. Carpenter and E. F. Miller, professors of engineering, came as representatives of the steam boiler users; E. D. Meier and Richard Hammond brought in the fund of experience that only long experience in boiler manufacturing rendered possible; Chas. L. Hinton was particularly valuable to the Committee as a steel plate manufacturer and an investigator in the scientific manufacture of iron and steel plate, and Wm. H. Boehm, an insurance engineer, brought to the Committee valuable suggestions as a representative of the field of boiler inspection and insurance. The frontispiece shows portraits of the above members of the original committee.

NOMINATIONS FOR OFFICERS OF THE SOCIETY FOR ELECTION IN DECEMBER 1915

The Constitution of the Society in C 47 provides among the Annual Committees:

"A Nominating Committee appointed by the President."

It further provides in C 48

A "Special Nominating Committee: Twenty or more persons entitled to vote may constitute themselves a Special Nominating Committee, with the same powers as the Annual Nominating Committee."

The procedure in the nominations for office is provided in the following By-Laws:

B-27 "A Nominating Committee of five members, not members of the Council, shall be appointed before February first of each year by the President. The Secretary shall publish the names of this Committee in the March issue of The Journal together with a request to the voting membership of the Society that they recommend to the Committee the names of eligible persons for the elective offices to be filled at the next election. This Committee shall deliver to the Secretary in writing between the first and the fifteenth of June the names of its nominees for the various elective offices next falling vacant under the Constitution, together with the written consent of each nominee. The names of the nominees for the various offices proposed by this Committee shall be published by the Secretary under the names of the Committee in the July issue of The Journal."

B-28 "A special Nominating Committee, if organized, shall on or before October fifteenth, present to the Secretary the names of its nominees for the elective offices next falling vacant under the Constitution, together with the written consent of each nominee. The names of the nominees for the various offices proposed by this Committee shall be published by the Secretary under the names of this Committee in the November issue of The Journal."

The President has appointed the following Nominating Committee:

Messrs. Edwin M. Herr, *Chairman*
Fred J. Miller,
Richard H. Rice,
Walter M. McFarland,
Edward C. Jones.

There are to be elected in December next

A President to hold office for one year

Three Vice-Presidents to hold office for two years

Three Managers to hold office for three years

A Treasurer to hold office for one year

Under the terms of By-Laws B-27 and B-28 the voting membership are requested to send to either or both of the Nominating Committees, in care of the Secretary of the A.S.M.E., 29 West 39th Street, New York, N. Y., their recommendations of names for any or all of the elective offices to be filled at the next election.

These recommendations should be sent in early and not later than June 1st.

COUNCIL NOTES

At a meeting of the Council on February 13, 1915, the Secretary reported the appointment by the President of the Nominating Committee for Officers for 1916, to consist of E. M. Herr, Chairman, Fred J. Miller, Richard H. Rice, W. M. McFarland and E. C. Jones. The Committee on Administration, referred to in these minutes in The Journal for January, was announced to consist of R. M. Dixon, Chairman, L. P. Alford, George M. Basford, George M. Forrest and J. W. Roe.

The appointment of Park A. Dallis as Honorary Vice-President to represent the Society at the inauguration of Edward Kidder Graham as President of the University of North Carolina was approved.

George L. Rockwood presented personally to the Council a letter of invitation to the membership of the Society to be present at the Fiftieth Anniversary of the foundation of Worcester Polytechnic Institute as a school of industrial science. The invitation was accepted by the members of the Council. The letter appears in this issue of The Journal.

The report of the Committee to Formulate Standard Specifications for the Construction of Steam Boilers and Other Pressure Vessels and for their Care in Service was presented and approved with the following resolutions:

RESOLVED: that the report of the Committee to formulate Standard Specifications for the Construction of Steam Boilers and Other Pressure Vessels and for their Care in Service be received as presented in corrected galley proof and that it be printed in The Journal, and in the Transactions, and also in pamphlet form as part of the Transactions.

VOTED: that the Boiler Code Committee and the Advisory Committee be continued for one year as one committee, instead of separated as formerly, and to be known as the "Boiler Code Committee."

The Council expressed its appreciation of the unprecedented amount of time and work which the various members had given to the preparation of this report and for the splendid results.

It was voted that the report of the Committee on Standards for Cross-Sections and Symbols be received and printed in the Transactions and that the committee be discharged.

It was voted to accept the report of the Committee on Special Threads for Fixtures and Fittings covering rolled thread screw shells, which was presented by the Secretary, and that it be printed in the usual way and come up for discussion at the next Spring Meeting.

It was voted to approve amendments to the By-Laws relating to the Nominating Committee for officers and a Special Nominating Committee. The text of these appears in this issue in the notice of Nominations for Officers of the Society.

The following appointments on local committees

were approved: Committee on Meetings in St. Louis, Edw. Flad, Chairman, George R. Wadleigh, F. E. Bauseh, E. R. Fish, E. L. Ohle; as additional members on St. Paul-Minneapolis Committee, Max Toltz and H. F. Mueller.

CALVIN W. RICE, *Secretary*.

SIR WILLIAM H. WHITE MEMORIAL FUND

The movement recently started by the leading engineers of England to erect a suitable memorial to Sir William H. White, the eminent engineer, has culminated in the appointment of a Memorial Fund Committee. This Committee has decided upon a memorial tablet with medallion portrait, to be erected in the building of the Institution of Civil Engineers in London, as one form in which honor to Sir William will be made manifest. The members of this Society will be given an opportunity to express their interest by contributing to the tablet fund, and a committee has been authorized by the Council to secure subscriptions. This committee consists of Jesse M. Smith, Alex. C. Humphreys and Frederick R. Hutton, and subscriptions may be sent to the Secretary.

CONFERENCE ON SCREW THREAD TOLERANCES

On February 5, 1915, a large meeting was held in the rooms of the Society on the general subject of limits for the dimensions of the threads of screws and taps.

For more than two years this Committee of the Society, of which Mr. L. D. Burlingame is chairman, has been at work on the general subject of Tolerances For Screw Thread Fits, and the subject has had the detailed attention of a sub-committee consisting of Messrs. A. A. Fuller, Ellwood Burdall and F. O. Wells. It was under the auspices of this sub-committee that the meeting of February 5 was called.

There were over forty in attendance, representatives of manufacturers of screws, taps and dies as well as the users, of such products and of organizations interested. A number of the largest firms in the country, both manufacturers and users were represented and also the engineering departments of both the Army and Navy.

Mr. Burlingame presided at the meeting. The committee had prepared an abridged report for distribution and there was a general discussion of limits of tolerances that would be recommendable with regard to pitch diameter, root diameter, outside diameter, lead and angle. Various opinions were expressed as to the desirability of specifying limits for more than one grade of work, i.e., a very close limit for the high grade of screw and a wide limit for screws to be used in rough work; also, whether differences in the specified limits should be made in the tap, or in the

screw. As a result of the conference, an Advisory Committee of three was appointed, consisting of Messrs. E. H. Ehrman, E. A. Darling and C. D. Young. This committee will confer from time to time with the regular committee upon the various questions which arise in this complex problem. Further, those who were in attendance at the meeting and others who have expressed their interest in the subject will be kept informed with regard to the progress of the work upon the report and, through their understanding of the situation as a result of the discussion at the meeting, should be in a position to render helpful suggestions.

This meeting is an example of the policy of the Society of conferring as widely as possible with representative men who are most vitally interested in any question affected by reports which are being formulated, with a view not only to securing the benefit of their experience, but the widest possible co-operation and unanimity of opinion. Meetings such as this tend to abolish misunderstanding and the consequent difficulties in establishing standards and greatly increasing the effectiveness of the work which the committees of the Society are accomplishing.

FIFTIETH ANNIVERSARY OF WORCESTER POLYTECHNIC INSTITUTE

Worcester Polytechnic Institute, Worcester, Mass., is to be congratulated on having reached the point where it is to celebrate the 50th anniversary of the granting of the charter for the school. The celebration will occur on Wednesday, June 9, during the commencement period. It is expected that the President of the United States will be present and through the attendance of prominent engineers and the representatives of various organizations the day will be made a celebration of the achievements of engineering and science as well as an anniversary of the Institute.

At the February meeting of the Council of The American Society of Mechanical Engineers, Mr. G. I. Rockwood presented personally a letter of invitation to the Society which was accepted with pleasure and is herewith transmitted to the membership:

Worcester, Mass.
Feb. 12, 1915.

TO THE COUNCIL OF
THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS,
29 W. 39th St.,
New York.

Gentlemen:

On the 9th of next June the Worcester Polytechnic Institute will celebrate the 50th anniversary of its foundation as a school of industrial science. The Trustees and Faculty have constituted the undersigned members of the society, who are also graduates of the Institute, a special committee to invite most cordially all members to visit the Institute on that day.

There will be an opportunity to meet great engineers and great men. Among others, Colonel Goethals has accepted our invitation. The President of the United States, who was the commencement orator twenty-five years ago, has expressed a desire to be present. In addition to the academic and social

events, a meeting of engineers is to be held, papers by members of the society will be read, and interesting processes of manufacture at various engineering works will be open to inspection.

Above all, however, there will be the chance to study the character and facilities of the Worcester Polytechnic Institute itself, to see its commercial shops, foundry and power house in operation and observe at first hand the methods of a unique experiment in engineering education which has continued for nearly half a century, having as its object the development of engineers who even in their youth are substantially prepared to share in the responsibility of handling commercial engineering problems.

The Institute really stands almost alone in providing its graduates with a practical training in the scientific management of industry, a subject discussed so often and so forcibly by the membership of this society. The student not only studies the kinematics and statics of machinery, and the nature of its parts, in the class room; the materials of construction in the chemical and physical laboratories; the thermodynamics of gases in the class room and engine room; but he performs work in commercial shops, foundry and power plant, on commercial machines, working factory hours alongside skilled mechanics. He not only hears lectures on the theory of business and shop management, but he handles and becomes familiar with such things as cash books, ledgers, time cards, pay rolls, shop reports, shipping receipts, balance sheets, and contracts. Different systems of time cards routing cards and cost systems can be tried out in the shops under real conditions, and the student becomes aware of every element of cost and of its relative importance in the price of an article of manufacture.

Men who have a natural ability for managing find after taking this course at Worcester that it has given them a tremendous start; that it has bridged for them the gap between their regular college course in "raw" engineering science, on the one side, and their practical usefulness, on the other. Their shop training work has been as near actual experience as it is possible for them to get.

It is commonly believed that such a mixture of theory and practice as this does not lend itself to courses of study in a professional school. The key, however, to success is the possession of adequate commercial shops within the direct control of the institution; and although the Department of Mechanical Engineering at Worcester provides all of the foregoing practical instruction in the regular course leading to the degree of B.S. in that department, it nevertheless does not fail to give as many hours devoted to pure physics, pure mathematics and those studies ordinarily called the humanities as are required by any other engineering school in this country; so that nothing in the way of high scientific attainment is sacrificed in order to secure time for these other no less important practical studies.

If the society's well known interest in the problem of modern scientific industrial education shall insure the presence of a large representation in June, it will add greatly to the success of the occasion.

G. I. Rockwood, Chairman. { *Entertainment*
R. Sanford Riley { *Committee.*
Victor E. Edwards { *Am. Soc. M. E.*

SAN FRANCISCO MEETING

A meeting of the Society is to be held in San Francisco on September 16 and 17, in connection with the Pan-American Exposition which had its formal opening on February 15.

For the benefit of those who will attend a special train schedule will be arranged over the Southern Pacific. It is planned to pick up at New Orleans those members who will start from the Middle West or South and other points further West than New York.

According to the schedule as at present arranged, the

party will leave New York either Thursday evening, September 9, or Friday evening, September 10, and will stop at Niagara Falls, the Grand Canyon and possibly Colorado Springs. The Hotel Clift has been selected as the headquarters of the Society during the meeting.

An International Engineering Congress will be held in San Francisco from September 20 to 25.

ADDITIONAL GREETINGS

The president of The American Society of Civil Engineers, Prof. Chas. D. Marx, lives in California and thus was unable to speak for his society at the meeting for establishing the Engineering Foundation. He had asked Mr. Clemens Herschel to represent the Society, who by misadventure was also prevented from attending, but who has sent in what, if present, he had intended to say. Mr. Herschel writes:

I believe I convey to you the unanimous desire of our members, when, in their behalf, I am wishing a great future for the Engineering Foundation and am bringing a great measure of thanks to its founder.

The Society appreciates the honor of being allowed to take a part in these exercises, and in the future administration of the Foundation. We here can say to the generous donor, paraphrasing what Latimer said to Ridley:

"Be of good comfort, Master Swasey, we shall this day light such a candle, by God's grace, as I trust shall never be put out."

APPLICATIONS FOR MEMBERSHIP

Members are requested to scrutinize with the utmost care the following list of candidates who have filed applications for membership in the Society. These are sub-divided according to the grades for which their age would qualify them and not with regard to professional qualifications, i. e., the age of those under the first heading would place them under either Member, Associate or Associate-Member, those in the next class under Associate-Member or Junior, while those in the third class are qualified for Junior grade only. The Membership Committee, and in turn the Council, urge the members to assume their share of the responsibility of receiving these candidates into the Membership by advising the Secretary promptly of any one whose eligibility for membership is in any way questioned. All correspondence in regard to such matters is strictly confidential and is solely for the good of the Society, which it is the duty of every member to promote. These candidates will be balloted upon by the Council unless objection is received before April 10, 1915.

NEW APPLICATIONS

FOR CONSIDERATION AS MEMBER, ASSOCIATE OR ASSOCIATE-MEMBER

ALBIN, LELAND D., with Ingersoll-Rand Co., New York
ALCOCK, GEORGE W., Engrg. Dept., American Locomotive Co., New York
BARTLETT, D. DANA, Cons. Engr., Sloan, Huddle, Fensel & Freeman, Madison, Wis.

BARR, CLARENCE D., Ch. Engr., American Cast Iron Pipe Co., Birmingham, Ala.

- WHITE, KENNETH, Engr., By-Products Coke Corp., Chicago, Ill.

SUMMARY

New applications..... 101

IRON AND STEEL SESSION

SIMULTANEOUS with the afternoon session of the Public Service meeting, a professional session was held devoted to iron and steel topics. Three papers were presented followed by a topical discussion on alloy steels and kindred subjects. The meeting was unusually successful as it was well attended and continued for over three hours. The papers presented were as follows: *Factors in Hardening Tool Steel*, John A. Mathews and Howard J. Stagg, Jr. (Contributed by the Subcommittee on Iron and Steel); *Standardization of Chilled Iron Crane Wheels*, F. K. Vial (Contributed by the Subcommittee on Hoisting and Conveying); and *The Mechanical Elimination of Scams in Steel Products*, Notably Steel Rails, R. W. Hunt.

FACTORS IN HARDENING TOOL STEEL

BY JOHN A. MATHEWS, SYRACUSE, N. Y.

Member of the Society
and

HOWARD J. STAGG, JR.,¹ SYRACUSE, N. Y.

Non-Member

The paper is devoted primarily to the practical side of the art of hardening and tempering tool steel, carbon steels being considered in the first place (0.60 to 1.50 per cent carbon).

The authors explain at some length the structural variations of steels as a function of carbon content and temperature, as well as the influence of the critical ranges of temperature on the properties of steel, with particular attention to volume changes (variation of expansion with temperature). In case of overheating, the first cooled portion is hardened first, forming an unyielding shell, and a strain is set up by the slower cooling interior which may lead to cracks and ruptures.

Time of Heating. The time of heating is of extreme importance for the strength of the piece: if the heating is too fast, the temperature through the piece will not be uniform, while long heating leads to the formation of abnormal size of grain and weakness of the metal. A very bad practice is quick heating in a furnace which is considerably hotter than the correct hardening temperature. The difficulty is that the thin parts, corners, and edges are liable to attain an overheated temperature before the larger portions of the piece attain the correct hardening temperature, and this overheating of the thin parts produces large grain size, abnormal expansion and tends to produce cracks.

Speed of Quenching. The metal must be cooled quickly, so as to obtain martensite, which is the correct constituent of hardened steel. The authors illustrate the influence of quenching by two examples which however are not tool steels, and after mentioning, ac-

cording to Benedicks,² the conditions which a liquid must have to exhibit a good quenching power, proceed to report their own tests of various quenching media which included pure water, brine solutions, and various oils. The results obtained are expressed in the form of curves.

In attacking the problem, the following method was adopted: A test piece of the dimensions shown in Fig. 1 was machined from a solid bar, and a hole drilled through the neck to within an equal distance from each side and bottom of the test piece. Into this hole a calibrated, platinum-rhodium couple was inserted and the leads connected to a calibrated galvanometer. The test piece was then immersed in a lead pot, also containing a thermo-couple to the point A, and the lead pot was maintained at a temperature of 1200 deg. Fahr. When the couple inside the test piece was at 1200 deg. Fahr., and the couple in the lead pot read 1200 deg. Fahr., the test piece was removed and quenched to the point B in 25 gal. of the quenching medium under consideration. At the start the quenching medium was maintained at room temperature. The time in seconds that it took the test piece to fall from a temperature of 1200 deg. Fahr., to a temperature of 700 deg. Fahr., was noted by the aid of a stop-watch. It is clear that immersing the test piece in the quenching medium raised the temperature of the medium. The test piece was then replaced in the lead, heated to 1200 deg. Fahr., quenched into the medium at this higher temperature and the time again taken with the stop-watch. These operations were continued until the quenching media, in the case of oils, had attained a temperature of about 250 deg. Fahr. The results obtained, time in seconds, for a fall from 1200 deg. Fahr. to 700 deg. Fahr., were plotted against the temperature of the quenching medium and a series of curves as shown in Figs. 2 to 8 inclusive were obtained.

A consideration of the results is interesting. Pure water (Fig. 2) has a fairly constant quenching rate up to a temperature of 100 deg. Fahr., where it begins to fall off. At 125 deg. Fahr., the slope is very marked. Brine solutions (Fig. 2) have both a quicker rate of cooling and are more effective at higher temperatures than water. The curve does not begin to fall off seri-

Abstract of paper and discussion presented at the Annual Meeting, December 1914. Complete paper may be obtained without discussion, price 10 cents to members; 20 cents to non-members.

² Journal of the Iron and Steel Institute, 1908, II., p. 232.

ously until a temperature in the neighborhood of 150 deg. Fahr. is reached. Where water at 70 deg. Fahr., cooled the test piece in 60 sec., the brine solutions cooled it in 55 sec.

Oils are slower in their quenching powers than water or brine solutions, but the majority of them have a much more constant rate of cooling at higher temperatures.

The curves shown in Figs. 7 and 8 are for thick viscous oils somewhat similar to cylinder oils. These curves are particularly interesting in that they have

4 in. long were made from the same ingot in sizes increasing $\frac{1}{8}$ in. in breadth and thickness. The smallest was $\frac{3}{8}$ in. square and the largest $3\frac{1}{4}$ in. square. Three ingots of different analysis were shown and a series of test pieces made from each. The test pieces were heated in a semi-muffle furnace to a constant temperature quenched, and the Brinell hardness test made. Each series was then drawn to 600 deg. Fahr. in a salt bath and Brinell tests again taken and then reheated to 1200 deg. Fahr. in a salt bath and Brinell hardness tests again run.

FIG. 1 TEST PIECE USED IN QUENCHING TESTS

FIG. 3 QUENCHING POWER OF BRINE SOLUTIONS

slower quenching abilities at low temperatures than at higher temperatures.

A comparison of curves in Figs. 4 and 5 shows the variation in quenching power of the same oil due to continued service. The differences in quenching rates may well account for different results from the same steel in different shops, or in the same shop due to change of oil used.

Hardness as Affected by Mass. Figs. 9 to 12 inclusive show results from quenching different masses of the same material under like conditions. Test pieces

It will be noted that the smaller the sample the greater the figure of hardness, indicating that the smaller sections are cooled with greater rapidity than the larger. The same agencies are at work in tool steel. The larger the mass the smaller the depth of hardness when quenched under similar conditions. In order to produce the same amount of hardness in a small and large section it is necessary to heat the larger section hotter than the smaller. A commercial application of this phenomenon will perhaps be interesting. The authors were recently confronted with the

problem of finding out the correct temperature for hardening tools made from the same steel in sizes varying from $\frac{1}{16}$ in. diameter to $\frac{3}{4}$ in. diameter. The temperature-size curve shown was finally adopted (Fig. 13). In other words, a $\frac{3}{16}$ in. round will harden at 1395 deg. Fahr., while a $\frac{3}{4}$ in. round bar should be heated to 1450 deg. Fahr.—a difference of 55 deg. Fahr.

Time and Degree of Drawing Temper. After the hardening operation has been safely performed, the next important step is that of drawing the temper. This operation is necessary for two important reasons:

- a The relieving of abnormal strains set up due to the quick contraction or expansion.

constant temperature for five minutes, fifteen minutes, etc.

Elastic Limit	Maximum Strength	Elongation	Reduction	Brinell	Remarks
228,750	260,137	2.5		425	1550-oil-800 deg. Fahr. 8 min.
204,125	211,562	11.6	45.4	390	1550-oil-800 deg. Fahr. 20 min.
175,000	183,187	12	49.35	340	1550-oil-800 deg. Fahr. 40 min.

A study of the table shows that time at the drawing temperature has a marked effect. The act of breaking down the martensite is progressive and not sharply de-

FIG. 5. QUENCHING POWER OF PRIME LARD OIL IN USE TWO YEARS.

FIG. 6. QUENCHING POWER OF RAW LINSEED OIL.

- b The breaking down of the extremely hard and brittle structure of the quenched steel.

The drawing of the temper begins to break down the true martensitic structure and as the temperature increases there are formed intermediate micro-structures between martensite and pearlite, first troostite, then sorbite, and finally pearlite.

Professor Heyn has published some valuable results on the decrease of hardness on tempering. The results are expressed in per cent of the original hardness.

100 deg. cent.	2.5 per cent.	400 deg. cent.	70.0 per cent.
200 deg. cent.	14.0 per cent.	500 deg. cent.	87.5 per cent.
300 deg. cent.	41.0 per cent.	600 deg. cent.	97.5 per cent.

Regarding the effect of time on drawing the temper, standard $\frac{1}{2}$ in. round A.S.T.M. test pieces were quenched from constant temperature into the same medium, and the temper drawn in same salt bath at

fixed. Both time and temperature have their effects.

The greater the initial hardness of the piece, the more marked is the effect of drawing the temper. By referring to Figs. 9 to 12 inclusive the actual values in Brinell hardness are shown. The piece of 0.25 carbon nickel, $\frac{5}{8}$ in. sq., quenched in oil, shows a Brinell of 360; drawn to 1200, a Brinell of 223. The per cent decrease in hardness is 61. The piece of $\frac{3}{4}$ in. sq., quenched shows a Brinell of 208; drawn to 1200 deg. Fahr., Brinell 183, showing a decrease in hardness of only 13 per cent.

Many years ago, one of the authors made several hundred hardening experiments and several thousand measurements to study the change of shape. The materials used were cylinders of steel and taps. Crucible steel alone was examined and the following variables were considered: (a) the effect of original form or

diameter upon the diameter after hardening; (*b*) the influence of carbon on change of form; (*c*) the influence of initial temperatures at quenching; (*d*) the influence of length of time of heating; (*e*) the influence of repeated hardenings, and (*f*) the effect of annealing previously hardened steels, upon change of shape in rehardening. Obviously when plain cylinders of steel are considered, there are four possible changes of shape, expansion in length and diameter, contraction in length and diameter, expansion in length and contraction in diameter, and contraction in length with expansion in diameter.

Under the influence of the variable conditions mentioned above, all four changes were actually produced.

FIG. 7. QUENCHING POWER OF NO. 1 DARK TEMPERING OIL.

Steel was also found which expanded in length on first hardening and contracted indefinitely thereafter on repeated hardenings. Another steel expanded in length on two hardenings and contracted on the next two. In a variable carbon series of steels from 0.50 to 1.33 per cent carbon, the magnitude of the change in length after four hardenings, increased as the carbon increased. For the same series it was noted that the volume changes were greater when hardening annealed rather than mannealed bars. The increase in length is greater the higher the hardening heat for all carbons.

These tests emphasize the fact that variable conditions produce variable results. It is of vital importance that steel be furnished uniform, chemically as well as physically, and it is equally important that the user employ every possible refinement in the handling of his

product. It is only under varying conditions of heat, size, time, composition, etc., that the results vary. Different steels will not behave alike in all cases, but it is a simple matter to determine under any given set of conditions how a particular steel will behave. Other things being equal, therefore, the original composition, grain size, condition of annealing and the method of manufacture affect the resulting changes in form after hardening. Above the decalescence point, the coefficient of dilatation increases proportionately with the carbon and for all carbon percentages the rate of dilatation increases with the temperature. Resulting changes of form are conditioned by the original proportions of the piece quenched, by its chemical compo-

FIG. 8. QUENCHING POWER OF SPECIAL "C" OIL.

sition, by the temperature from which it is quenched, and within certain limits by the time of heating. Hardness, brittleness, change of form and liability to crack, generally speaking, increase with the carbon content and the temperature and time of heating. Nevertheless, constant conditions give constant results.

Constant conditions are not always attainable. The maker of steel cannot control conditions in his customer's shop and the customer cannot control conditions in the steel plant, and the human element must be considered in both. The properties described are inherent properties of carbon steel, and because of them many a dispute has arisen over tools lost in hardening. The placing of the exact responsibility is very difficult.

Furnaces and Methods of Heating. Much has been

FIG. 9

FIG. 10

FIG. 11

BRINELL HARDNESS OF TEST PIECES AFTER QUENCHING TO SHOW EFFECT OF MASS

said regarding the superiority of gas furnaces over oil furnaces and vice versa. The fuel used is immaterial for good practice so long as the following points are taken care of:

- a The furnace and hearth should be of sufficient size so as not to be affected materially in temperature by the introduction of the parts to be hardened.
- b The furnace should heat at a uniform rate.

- c The furnace should be of uniform temperature over its entire hearth.
- d The furnace should be run under neutral, or reducing conditions. A good rough test for this is the introduction of a piece of wood or paper upon the hearth. If the paper, or wood, burn, the atmosphere is oxidizing. If they char, reducing or neutral.
- e The temperature control must be at all times exact and it must be possible of exact duplication on repetition work.

A blacksmith's fire is satisfactory under good handling, but for constant work it is too exacting on the operator and requires too many manipulations to secure uniform and continuous results. To expect uni-

FIG. 12 BRINELL HARDNESS TO SHOW EFFECT OF MASS

FIG. 13 TEMPERATURE—SIZE CURVE FOR HARDENING TOOLS

formly good and consistent results from a hardener not provided with adequate or suitable equipment is unreasonable. When the question of good equipment in the way of furnace, quenching arrangements and media, pyrometers, etc., has been satisfactorily taken care of, the hardener still has plenty of variables to contend with which are beyond his control.

DISCUSSION

HENRY M. HOWE¹ in a written discussion particularly endorsed the use by the authors of their ingenious method of determining the rate of cooling of different liquids, a method which can be applied without the use of sensitive instruments, and is superior to that of Benedicks.

With reference to carbon, it should be understood that the pearlite and the excess of ferrite and cementite referred to are not always recognizable under the microscope. Under certain conditions they are apt to be all mixed in such a fine emulsion (called "sorbite") that they cannot be recognized individually.

Referring to the position of the critical temperature in carbon steels, it should be understood that the influence of manganese and nickel in lowering the transformation range is primarily through their increasing the hysteresis. When the decalcence points are determined, it is found that they have not been very greatly lowered, while the observed lowering of the recalcence point represents chiefly hysteresis.

Further, the writer indicated several additional authorities, especially the work of Benedicks, and approved of the results given in Table 1 on the penetration of hardness. In reality, the hardness of the corners and edges exceeds that of the interior of the piece even in a greater degree than these numbers would indicate, for the reason that when the Brinell ball is pressed into the specimen near its edge, and more particularly near its corner, its indentation is abnormally great because of the proximity to the side of the piece.

Figs. 9 to 12 indicate that our previous belief as to the completeness of annealing at 600 deg. cent. was incorrect, thus showing that what Goerens found for very low carbon steel, does not hold for hardening caused by rapid cooling. Similarly, the results in the table which show that at 430 deg. cent. the tempering was very far from reaching the maximum for that temperature even after a sojourn of 20 minutes, disagree with the earlier and very precise determinations of Barns and Strouhal who found that the tempering at these temperatures reached its maximum very quickly. One is at first tempted to refer the softening observed after the 20 minutes and the 40 minutes exposure of the authors to opportunity for coalescence of the sorbite, but it seemed to the writer that the loss of elastic limit and hardness is too great to be accounted for in this way.

J. J. RALPH in a written discussion called attention to the experiments on cylinders which expanded or contracted in length or cross-sectional area or both. The results coincide with some experiences of the writer with hypo-eutectoid steels of about 0.45 per cent carbon.

Finished pieces about 2 in. in diameter with 0.001 in. tolerance showed differences as much as 0.002 in. above high to

0.002 in. below low limit after hardening. It being quantity production, this was obviously very expensive, requiring either the scrapping of the piece or costly finishing of extremely hard surfaces. Closer observation showed it to be the result of variations in quenching temperatures. This pointed to a temperature at which the steel could be hardened and at which it would neither shrink nor expand. Instructions were given to the machine shop to hold the piece as closely as possible to the high limit and suitable care being given, 90 per cent was finally going direct through inspection to assembly. Further investigation showed that the facilities for measuring temperature were not delicate enough to allow the fine control necessary. Nor could it be sure that the steel was running evenly enough chemically (it was a low price openhearth low carbon, low phosphorus and sulphur) to allow the fixing of a definite range. Quenching conditions, both as to composition of the quenching material and its temperature were far from ideal, thus giving three variables which were unknown.

A case has come to light where this ideal was reached. The steel was about 0.6 per cent carbon. It involved control of temperature to within a total range of less than 5 deg. Fahr. considerably less than the instrument error of the best of indicating pyrometers and was only made possible by the use of a bath furnace and the resistance thermometer.

Skilled practical men, knowing the steel they are working with, are willing to guarantee almost a finished hardened piece exact to size and shape. A comparison of results obtained by several skilled smiths will show a surprising difference, probably owing to different kinds of steel they have been accustomed to handling. It must not be overlooked that the usual hardening room and machine shop conception of "exact" is far from perfect.

Investigation of hardening defects is not usually as thorough as it should be. It is hampered by ignorance of past conditions and the effect of previous operations, lack of knowledge of the steel used, human elements of feeling as to the money involved, responsibility, and a feeling that steel is steel and does what it does. Seldom is an attempt made to reproduce the defect thus proving conclusively what the cause was.

In his own work on long relatively slender pieces, the writer found most of his trouble in distortion due to bending in heating. Steel when hot seems to bend under the application of a steady, even, though slight load, the weight of the part being hardened often being sufficient to cause very noticeable distortion. Another case is initial condition of strain, either due to forging, rolling, machining or accident. When the bar is heated, the strains are relieved and there is a bending or twisting of the piece in readjustment. These are particularly annoying in fine work and in one case the substitution of square for round stock eliminated this trouble in a round machined piece.

If a practical way could be found to hold hardened pieces to size and shape, it would be possible to do all of the machining with the piece soft. A very material shop saving would be obtained and it would also allow the use of parts with physical characteristics as we would like to have them instead of makeshifts in many places. The problem has been simplified within the past year by the introduction of the potentiometer type pyrometer with a possible commercial accuracy in skilled hands of about one deg. Fahr.

¹ Columbia University, New York.

O. R. CARY¹ stated that he had occasion to produce a number of die blocks of the average size of 5 by 3 by 1 in. These were treated in an electric resistance furnace. It was found that if a certain size was heated in 44 minutes to the proper point, as indicated by the passage of that piece through the transformation point by about 20 or 25 deg., a die was obtained which required no further chemical treatment. A cut of less than a thousandth of an inch cleared it perfectly. If it was heated in 38 instead of 44 minutes, a cut of at least four-thousandths was required to clear the surface, with similar changes in shape. This period of 44 minutes happens to be the constant for this particular furnace; for some other furnace it undoubtedly would be different. But it has been proved that if you vary the point of heating ordinary carbon commercial steel by as much as 5 per cent, you have varied the shape of your piece perceptibly.

A great many of the troubles in the treatment of such masses of metal have been laid either to steel or to pyrometers.

BRADLEY STOUGHTON expressed his appreciation of the paper and said that if it should result in reducing to a science some of the rules of thumb with which steel tempering men are accustomed to work, it would be a great help. He was particularly interested in the experiments outlined on the effect of mass. Those who have tempered large pieces of steel have noticed one difficulty which occurs occasionally, particularly in dies. If the die is large so that the mass of the metal is considerable there is liable to be a soft zone of metal immediately under a very hard exterior so that the die will frequently drop, as they call it. This has undoubtedly been explained by the author and by Professor Howe. The exterior of the metal cools and shrinks in the interior; then the interior in its cooling shrinks away from the hard exterior which will naturally produce a zone of soft metal. He hoped that the author and his associates might throw some light on a better quenching medium for steel of large mass.

JOHN A. BRASHEAR by way of illustration of the extreme refinement required in the treatment of steel in order to secure homogeneous material, said that 10 or 15 years ago he was asked to make a rotating mirror to determine not only the velocity of light, or redetermine it, but for the purpose of determining the variation of the speed of the various wave-lengths, if possible. The mirror was to rotate some 30,000 revolutions per minute and its four sides had to be located so that they were absolutely equi-angular with the surfaces. The image of a star thrown on the surface of one of the sides had to go about three miles away and then come back without being distorted, which illustrates the extreme accuracy required. Not only was great difficulty experienced in the mechanical problems involved, but also in getting homogeneous surfaces of a standard quality of hardness so that each surface would polish the same. If one spot on the surface was a tiny little bit different from any other spot, the surface would be a little low where it was softer and a little high where it was harder. The work, however, was finally accomplished and the mirror has been used for making a number of light determinations.

THE AUTHORS answered numerous inquiries during the Leeds and Northrup Company, Philadelphia.

discussion regarding various points in the paper upon which further information was desired. Mr. Stagg in response to the request of the chairman for a topical discussion upon alloy steels supplementing the information given in the paper, showed a number of interesting lantern slides of microphotographs of alloy steel and explained their characteristics.

STANDARDIZATION OF CHILLED IRON CRANE WHEELS

BY F. K. VIAL,² CHICAGO, ILL.

Non-Member

This paper presents the results of an extended investigation of the whole subject of chilled iron wheels for cranes. Because of the great quantity of summarized and tabulated data which the paper contains, it is not possible to prepare a comprehensive abstract to come within the space available. What follows, therefore, is in the nature of a synopsis of the paper.

In the earlier stages of crane construction, wheels of the general design used in railroad service were adapted to crane service by adding a second flange of about the same section as that of a railroad wheel. This practice worked very well as long as the wheel loads did not exceed those used in railway service. In the heavy types of bridge cranes, however, concentrated wheel loads five times as great as occur in railroad service are required to secure the greatest economy.

The most common troubles with crane wheels are:

- a. Wheels becoming out of round on account of unequal wear.
- b. Breaking down of metal on account of loads exceeding its bearing power
- c. Distortion and binding of flanges on account of irregularity in gage of track.
- d. These defects in wheels produce heavy strains throughout the structure, including worn and broken propelling gears.

All of these defects are not only annoying but expensive on account of the interruption of service of important machinery.

The Griffin Wheel Company has undertaken an investigation into these various phases by testing to destruction a large number of full size wheels of various designs in the R. W. Hunt & Company's 300,000-lb. Riehle testing machine. Use was also made of a considerable number of tests made at Purdue University and at the University of Illinois.

The items established are:

- a. The relation of the bearing power of chilled iron, to various types of steel rails.

¹ Griffin Wheel Co.

Abstract of paper and discussion presented at the Annual Meeting, December 1914. Complete paper may be obtained without discussion, price 20 to members; 10 cents to non-members.

- b The carrying capacity of various rails.
- c The relation of the diameter of wheel to traction.
- d The relation of diameter of wheel to flange strength.
- e The relation of flange thickness and tread thickness to flange strength.
- f Standardization of designs for all diameters of crane wheels.

Bearing Power of Chilled Iron on Steel Rails. The vertical load to be carried on any wheel is not limited by the capacity of the wheel, but by the carrying capacity of the rail. The bearing power of chilled iron

TABLE 1 CONTACT AREAS AND PRESSURES

Load in Lb.	33-In. Chilled Wheel		44-In. Steel Driver	
	Contact Area	Pressure per Sq. In.	Contact Area	Pressure per Sq. In.
5,000	0.07	71,500	0.07	71,500
10,000	0.12	83,300	0.13	66,700
15,000	0.16	93,750	0.19	79,000
20,000	0.22	90,900	0.25	80,000
25,000	0.27	92,600	0.30	83,300
30,000	0.35	85,750	0.36	83,300
40,000	0.40	100,000	0.47	85,000
50,000	0.44	113,600	0.50	100,000
60,000	0.57	105,000	0.68	88,300

FIG. 1 PERCENTAGE OF TRACTIVE FORCE REQUIRED FOR VARIOUS DIAMETERS OF WHEELS COMPARED WITH 33-IN. CHILLED IRON WHEELS

is far in excess of that of a steel rail, and, therefore, may be neglected when considering maximum vertical loads.

The tests show that under like loads, the depression in the rail is inversely as the diameter of the wheel. The larger diameter of wheel makes a larger area of contact, which reduces the pressure per square inch.

The following table shows that the mean intensity of the stress over the area of contact was about 100,000 lb. per sq. in. for the chilled wheel and 86,000 lb. for the steel driver.

Analysis of the Carrying Capacity of Various Rails. Tables are given to show that on a new A.S.C.E. rail the safe maximum limiting load for a 12-in. wheel is 23,000 lb., and for a 33-in. wheel, 38,150 lb. If the top of the rail is flat, 2 in. wide, the limiting load on 12-in. wheels is 78,300 lb. and on 33-in. wheels, 130,000 lb. One of the tables gives also the carrying capacity

of the rail only, without reference to the strength of the wheel.

Relation of Diameter of Wheel to Traction. The power required for locomotion decreases as the diameter of wheel increases.

FIG. 2 CURVES SHOWING EFFECT ON FLANGE STRENGTH PRODUCED BY INCREASE IN WHEEL DIAMETER

A 24-in. wheel requires 25 per cent more power than a 33-in. wheel.

A 16-in. wheel requires 68 per cent more power than a 33-in. wheel.

Fig. 1 shows graphically the relation between the variation in the diameter of wheel, and tractive force required. It appears that the 24-in. wheel would require 25 per cent more power and the 16-in. wheel 68 per cent more power than the 33-in. wheel under these conditions.

As regards the safe loads and deflections of rails. From the bearing tests made, the average depression due to bearing alone was 0.0029 in. per 10,000 lb. load :

$$0.0029 \times 13.7 = 0.0397$$

Combined deflection and depression, 0.0497.

Relation of Diameter of Wheel to Flange Strength. The strength of flanges increases with the increase in diameter of wheel. With the same dimensions of flange and tread the flange on a 33-in. wheel is from 26 per cent to 34 per cent stronger than the flange on a 24-in. wheel and from 62 per cent to 92 per cent stronger than the flange on a 16-in. wheel.

The failure of wheels occurred in what may be called two stages. The first failure represents the ultimate strength of the chilled or white iron. The ultimate failure represents the rupture of the grey iron. The coefficient of elasticity is evidently different in the two kinds of iron, and the necessity for backing up the chilled iron with grey iron is clearly indicated. The curves in Fig. 2 show that from the $1\frac{1}{4}$ -in. flange to the $2\frac{3}{4}$ -in. flange, the rate of increase in strength is higher with each successive flange thickness.

Relation of Flange Thickness and Tread Thickness to Flange Strength. The tests show that the relation of flange thickness to throat thickness for crane wheels should be as two is to three. Assuming the strength of a flange $1\frac{1}{4}$ in. thick and throat thickness of $17\frac{3}{8}$ in. as 100, a flange having a thickness of $1\frac{3}{4}$ in. and throat thickness of $25\frac{3}{8}$ in. would be 200. In other words, every $\frac{1}{8}$ in. added to flange thickness with the relative increase in throat thickness increases the flange strength 25 per cent. Chilled iron flanges were tested to above 1,000,000-lb. horizontal pressure without breaking.

The value of chilled iron for wheels to carry the heaviest concentrated loads is being more and more recognized. This is shown in crane work and other locations where loads of 100,000 lb. and upwards are required per wheel. An inquiry from a U. S. Navy Yard for 38-in. wheels for use under a heavy traveling crane reads as follows: "The steel wheels have been so unsatisfactory that it led us to inquire of you relative to the furnishing of regular chilled cast iron wheels for this purpose." Chilled iron wheels were furnished and have served with satisfaction for three years. This indicates that for heavy concentrated loads, chilled iron has superior qualities, and that the only limit to car capacity is the ability of the rail to carry the load.

Hitherto a good many crane builders have used the standard M.C.B. flange on wheels for crane service. This certainly is not correct, for in railroad service the thickness of flange is limited on account of crossings, switches, guard rails, etc., while in crane service, where the load carried by the wheel and the resulting flange pressure is several times greater than encountered in railroad service, there is unlimited space for de-

signing flanges in proportion to the work which they must perform. Furthermore, for heavy cranes where the expense of changing wheels is large, and in case of renewals keeps the crane idle, an ample factor of safety should be used. This is also essential on wheels having two flanges, when the rail is out of level, giving excess work on one wheel, or the track is out of alignment, which changes the track gage, and one flange receives considerably more stress than calculated.

FIG. 3. RELATIVE STRENGTHS OF FLANGES FOR VARIOUS THICKNESSES

Standard Design for Crane Wheels. Various designs of 12-in. to 36-in. double flange wheels were made, giving the maximum safe vertical load and the maximum safe flange pressure for each design. Full details of each wheel are shown in the paper.

The maximum vertical load given does not exceed the maximum stress that should be applied on the various steel rails shown in connection with the wheels.

In analyzing the metals available for the manufacture of wheels for crane service, the definite conclusion is reached that chilled iron has more desirable properties for heavy wheel service than any other known metal for the following reasons:

TABLE 2. SAFE STRENGTH OF CRANE WHEEL FLANGES AT A FACTOR OF SAFETY OF FIVE

Diameter Inches	Flange Inches	Throat Inches	Rad. Lb.	Strength

DISCUSSION

ARTHUR L. WILLISTON in commenting on the method described of finding the power required for locomotion by drawing a load up an inclined plane, called attention to the question of the friction of rolling between a smooth ground wheel and a smooth rail. The author had calculated this on the theory of the wheel running uphill. If the material were like lead, which is absolutely inelastic, that would be a correct way of calculating, in making the successive depressions in the rail as the wheel moves forward. With an elastic material like chilled iron, the condition is somewhat different. There is another force behind the wheel tending to push the wheel forward as the material tends to return to its natural condition. With a material like chilled iron running on an open hearth steel rail, from one-half to two-thirds of the work done in compressing the rails is returned by the elasticity of the materials.

W. A. BENNETT¹ who presented the paper in the absence of the author said in reply that the chilled iron used is so hard that it has no ductility whatever; while it is not claimed that the theory of a body rolling up an inclined plane is absolutely correct, it gives a result within working limits.

W. L. STORK² in a written discussion accompanied by lantern slides showing microphotographs of the structure of chilled iron car wheels said that chemical analysis and condition of casting are equally, if not more, important in the standardization of crane wheels than standardization of design. The design can have no positive influence upon the quality of wheel if the condition and composition of the iron put into the wheel are not studied.

The chemical analysis of the metal and length of time in service of the wheels are given in Table 3.

The microphotographs showed the structure of four different wheels two of which gave excellent service and two

lasted only a few months. They showed that there is a difference in structure in each wheel in passing from the chilled sections to the softer sections. Those of the good wheels show the metal hard, strong and dense. The metal of the other two wheels has a different structure. The chilling action also in the two good wheels was more severe and to a greater depth. With respect to the chemical analysis shown in the table, it is to be noted that the manganese, phosphorous and sulphur contents are the same for all wheels.

The higher the carbon content the greater the tendency for a graphitic structure; also the higher the carbon content the less is the change of chilling the casting. For high carbon contents the cooling and freezing cannot be rapid enough to retain all of the carbon in the combined form. Does not the chemical analysis and composition justify the metallography as shown in the photomicrographs? Are not the increase in graphite, the coarser structures and the decrease in cementite justified by the chemical composition?

TABLE 3. COMPOSITION OF WHEELS AND TIME IN ACTUAL USE

ALL WHEELS REMOVED DECEMBER 1, 1911						
No.	Total Carbon	Si.	Mn.	P.	S.	Months in use

13	2.60	0.52	0.51	0.390	0.140	118
18	2.62	0.50	0.53	0.300	0.153	111

AUGUSTUS SMITH, in a written discussion, stated that, though the author's paper is not always convincing, the tests on the strength of flanges is valuable, and the suggestion that crane wheels should be designed according to the strength of the flange seems to be a very logical method. Nevertheless the method of designing the wheel outlined can be followed for any agreed upon ratio of horizontal flange stress to vertical wheel load.

No experiments were made on tractive force. The tractive force required for wheels of different diameters is derived by the author by a mathematical analysis which neglects the elastic properties of the rail and wheel in regaining their respective contours after the load is relieved or passes along, which shifting of the load to successive portions of the rail and wheel even aids in restoring the depressed contour. In the writers opinion, the results given are incorrect.

A line of investigation is suggested which would be a more accurate method of testing rail and wheel resistance to vertical loads; tests in which the tractive force required to roll wheels on rails under different loadings and different diameters of wheels is measured directly. Tractive force should vary with the load and be practically independent of the diameter of the wheel, after correction for journal friction, as long as the rail and wheel are perfectly smooth and the load does not exceed the elastic limit of either rail or wheel. If such tests were made with a glass like unyielding wheel, the results would indicate the elastic limit of the bearing power of the rail. Another series of tests on a special rail of glassy hardness would indicate the elastic limit of the bearing power of different wheels made of softer material than the test rail.

THE MECHANICAL ELIMINATION OF SEAMS IN STEEL PRODUCTS, NOTABLY STEEL RAILS

BY ROBERT W. HUNT, CHICAGO, ILL.

Member of the Society

Increased weight of rolling stock and speed of traffic have led to increase in size of rail sections, requiring changes in the detail of rail manufacture. Under these conditions it is not surprising that new and unexpected physical weakness should develop in the heavier rails. One of the chief troubles has been failures through

FIG. 1 FACE OF AN INGOT AFTER HEATING WITH THE ADHERING SCALE REMOVED

crescent-shaped pieces breaking out of the rail flanges, followed by at least one, and in many cases several, ruptures across the whole section of the rail. Investigation showed that in practically every instance of such failure there was a more or less pronounced seam running longitudinally in the bottom of the rail near its center. This seam occurs at the top of the curve of the crescent-shaped break and is undoubtedly the point at which the fracture starts.

Abstract of paper and discussion presented at the Annual Meeting, December 1914. Complete paper may be obtained without discussion, price 10 cents to members; 20 cents to non-members.

As a result of an investigation of the subject, T. H. Mathias, assistant general superintendent of the Lackawanna Steel Company, determined that the most certain way of getting rid of seams was to remove that portion of the metal which contained them. He reasoned that the primary causes of seams existed in the ingots and probably were incident to the casting of the ingots. The surfaces of ingots display disk-like apertures, due to entrapped air, which in rolling could easily be elongated into dangerous seams. It was demonstrated, also, that the surfaces of the ingots are decarburized to the extent of eight to ten points carbon and to a depth of 5, 16 in., which must be detrimental to the finished product.

The removal of the surface metal is effected by a hot sawing, or milling operation during the process of rolling. The ingot is first reduced to a point where the product is 75 per cent finished, in the form of a partially shaped bar 60 ft. long, when it is entered between two pinch rolls with the flange side up and forced between two milling saws. A second set of rolls pulls on the bar and aids in holding it in line for the milling operation, for which purpose milling saws 5 ft. in diameter are used. Metal

FIG. 2 EFFECT OF PRACTICALLY ROUND IMPERFECTIONS WHEN ELONGATED BY 15 PASSES IN THE ROLLING MILL

is removed from the top and bottom of the bar, the main object being to eliminate the seams from the central portion of the bottom of the rail which has been the starting point of the moon-shaped failures, and to remove them from the top or bearing surface of the head of the rail.

In Fig. 1 is reproduced a photograph showing the actual size of a section of the face of an ingot as it appears after heating with the adhering scale removed. This view gives an illustration of how serious the disk-like apertures in the surface may be. As the section of the ingot is reduced and elongated in the rolling process, the apertures will be stretched longitudinally and formed into seams. Fig. 2 shows what would occur in that way to any practically round imperfections of the size indicated when elongated by 15 passes in the rolling mill. If so small an imperfection would give such a result, the seams resulting from larger ones would be proportionately greater and, therefore, more serious, both in length and depth.

In the operation of rolling, the ingot is reduced in the blooming rolls to an 8-in. by 8-in. cross-sec-

tion and after cropping the ends the bloom is further reduced in the roughing or shaping stand of rolls by five passes. A bar which will make four 33-ft. rails is at this point in the rolling operation about 60 ft. in length; therefore, the area of metal to be cut off or removed in the milling machine is approximately $\frac{1}{8}$ in. deep, 7 in. wide and 60 ft. long. It is driven through the pinch rolls at a rate of 60 ft. in 30 seconds. The pinch rolls have a draft of about $\frac{3}{8}$ in. and thus force the bar between the two milling saws, which are so arranged in the housing that they may be raised or lowered as desired. There is from $\frac{1}{32}$ to $\frac{5}{64}$ in. of metal milled from the head and base of the bar, the front end of which, immediately on passing from between the tools, is caught by a second set of pinch rolls which have a draft of about $\frac{1}{16}$ in. These pinch rolls force the bar between the tools, pull it from between them, and also hold it in practically perfect line for the milling operation. The milling apparatus is driven electrically and requires about 600 h.p. for its operation.

Fig. 3 shows an etched cross-section of the piece preparatory to its entering the milling machine, and on it is clearly shown the enveloping layer of lower

FIG. 3 CROSS-SECTION OF BAR PREPARATORY TO ENTERING MILLING MACHINE

carbon steel. Fig. 4 presents the shape of the bar after it leaves the milling machine preparatory to further reduction in the regular rail rolls.

Fig. 5 shows the milling operation in process. As the milled dust or particles of steel are thrown out, they are hit by water under pressure which forces them into a chute which discharges them below and also prevents the material from adhering together. Fig. 6 shows one of the milling tools. It is 5 ft. in diameter with an 8 in. width of face and revolves at a peripheral speed of 2500 ft. per minute, thus causing an engagement of about 400,000 teeth per minute on the hot rail bar. The teeth are 0.80 carbon steel, and it has been demonstrated that they will mill at

least 30,000 tons of material without requiring dressing. The one shown had milled about 15,000 tons.

Fig. 7 shows a piece of a rail broken under the drop press in which is plainly seen a pronounced seam in the flange directly under the center of its base, and is an illustration of a dangerous rail.

To illustrate the appearance of many ordinary steel rails of commerce when etched the author shows a collection of photographs of heads and flanges of rails of several different makers, including specimens

FIG. 4 APPEARANCE OF BAR AFTER IT LEAVES THE MILLING MACHINE

from the Lackawanna Steel Company which have been milled by the Mathias process. Four views are reproduced herewith in Figs. 8 and 9 which are characteristic and representative of those given in the paper.

DISCUSSION

H. C. HIBBARD felt that the paper might be considered as curing a thing which ought not to be present at all. More of the seams are the result of rubbing, but undoubtedly, at least some of them have started from those surface skin holes which really ought not to be there in good steel. The speaker stated that he is still old-fashioned enough to agree with Captain Hunt, who said once that he believed the way to make good steel, was to make good steel. Formerly, good steel used to be made by proper furnace management, proper care of the gases and proper care of the impurities; and ingots were made such that rails rolled from them were actually perfect and showed no seams. Split, there was nothing to them but clear, sound, solid steel from one end to the other, and from top to bottom, so that they did not require to be milled to be free from seams. None of the rail ingots which represent current practice are sound. They all have pipes and a number of them have blow-holes. The speaker realizes the difficulties which rail mills have to meet owing to the plants which they have, to produce solid ingots, but at the same time, he believes that until that is done and until the production starts with the solid, sound ingot, it will be impossible to get a sound, solid rail.

Properly made steel should have a full liberty to pipe and the pipe should not be reduced or eliminated by holes in the other parts of the ingot. In an ingot cast without any spe-

cial precautions, the only hole that should be there should be the pipe and nothing but the pipe. There are two well tested means of getting rid of the pipe and of securing a sound ingot. One is by lateral pressure, and the other by keeping the top of the ingot hot. A rail ingot will probably keep melted in the interior from $1\frac{1}{4}$ to $1\frac{1}{2}$ hr. according to its size, after it has been cast, and whatever means is applied to prevent the pipe, it should probably start within fifteen minutes after the ingot is cast and should be continued until

FIG. 5 HOT SAWING OR MILLING MACHINE IN OPERATION

the metal is all solidified. This being properly done, there will result a good, sound ingot, and such an ingot properly rolled will give a rail without seams.

J. D. HOWARD, in a written discussion, pointed out that the report of the Committee on Rails and Equipment of the National Association of Railway Commissioners, presented at its recent convention held in Washington, D. C., in dealing with the subject of train accidents, furnished statistics from which it appears that the average daily losses due to derailments alone, for a term of 10 years, were at the rate of 1.04 persons killed, 14.1 persons injured, and a property loss of \$15,900 per day. The total figures were 3,727 killed, 52,047 injured and property loss of \$57,192,396.

An amelioration of such conditions is demanded and it is believed that milling the running surfaces of the heads and the lower surfaces of the bases of steel rails will remove certain recognized defects, and thereby tend to lessen the number of rail failures and the casualties incident thereto. It is understood that no claim is made for other than surface defects. The writer had witnessed the process of milling the bars and Mr. Mathias, who made very modest claims for it, expects that milled rails now in service will within a short time demonstrate the efficacy of the method.

The presence of streaked metal in rails, including both interior and exterior streaks, and low carbon surface metal, have occasioned comments in reports upon tests of steel rails. Such a soft metal surface when located over a hard steel

core and exposed to wheel pressures at the running surface of the head, exerts an unfavorable influence, particularly when interior seaminess is present. It augments the wedging and splitting tendency of the wheel loads. Still earlier, Tests of Metals, 1909, showed a difference of 28 points in carbon between the center and the sides of the head of a 75 lb. rail.

Such occurrences are common and their frequency constitutes a sufficient basis for the claim advanced by Mr. Mathias that one of the features of his process consists of the removal of partially decarburized metal at the surface. There is less anxiety on account of the presence of decarburized surface metal at the base than at the head of the rail. Soft steel may even display the functions of a deterrent against the detrimental influence of seaminess in such places. Certain defects are negligible in soft steels which are serious in hard steels, such as slight serrations and indentations.

Streaky conditions in steel doubtless constitute serious problems for the steel maker. Such streaks are the cause of many rail failures, and they should be eliminated if it is feasible to do so. They tend to cause split heads and base fractures. The removal of such seams is a metallurgical question, in respect to which the steel makers do not offer great encouragement. Still, the case may be more hopeful than some statements would lead one to infer. Present information indicates that a more general state of interior seaminess exists in "A" rails over those of other parts of the ingot.

Referring to the investigation of rails conducted by the Commission, the metal of the heads and bases of a number

FIG. 6 A VIEW OF ONE OF THE MILLING TOOLS

of rails have been planed off to different depths, and a streaked state disclosed at each stage. Starting at the ingot, there is obviously no reason for expecting any different metal on the side which chances to become the head of the rail

over that which happens to be rolled into the base. Interior streaks in the metal of the head should have their counterpart in the metal of the base.

The examination of the metal in a 100 lb. rail of recent manufacture, an "A" rail, showed the presence of 22 seams in the metal of the head, ranging in length from $\frac{1}{2}$ in. to $5\frac{1}{2}$ in., and at various depths up to $\frac{3}{4}$ in. Some were at the surface, but generally they were most prevalent at depths of $\frac{1}{8}$ in. to $\frac{3}{8}$ in. below the running surface. Those of the base were found at depths up to $\frac{7}{16}$ in., measured from the lower surface, lengths from $\frac{1}{2}$ in. to $7\frac{1}{2}$ in., and in from the edge of the flange 1 in. to $2\frac{3}{4}$ in. Twenty-three of these base seams were disclosed in this rail. Other rails from other heats and other parts of the ingot were free from interior streaks, so far as disclosed by the examination.

M. H. WICKHORST¹ expressed his admiration of the bravery of Mr. Mathias in getting up a milling machine that will mill a hot bar 60 feet long and do it while the bar is going through the rollers. He believes, however, that the cause of the seams in the rail is somewhat different from what Captain Hunt stated it to be. The deep seams in the rail flaws which extend anywhere from 0.08 to 0.12, or possibly 0.15 of an inch deep from the surface, seem rather to start from cracks in the ingot. If the scale is removed so that the surface can be really seen, it becomes apparent that most ingots are more or less cracked. When the ingot is rolled, the seams tend to crack open, and the amount depends upon the draft in the rolling. With a large draft, this crack will open wide and there will be in the surface of the bloom a sort of a double "V"-shaped affair. This zigzag shaped crack opens up in the first pass, and in the next passes, the crack will modify into a double "V"-shaped flaw, one inside the other. Further rolling simply presses them together so that at the stage of the bloom 8 to 10 in. sq., there will be a flaw which looks like a "Y," the two sides having come together and some of the "V" flaw still remaining. Still further rolling will simply extend the "Y" flaws in the bloom, so that when they come to a rail, or a small billet, there will be a very much elongated "Y," or generally a series of them together.

An interesting fact is that it seems that these flaws occur mostly on what are known as the two open sides of the ingot as it first enters the rolls. On the top and bottom sides, where actual compression is applied, the ingot probably tends to heal up. In this way, it may be possible to manage so that these seams will occur mostly in the thread, or the bottom, or the base of the rail, and the thought has occurred further that this can be made use of practically. Apparently seams that occur in the web, or top of the head, do not result in rail fracture, while those which occur in the base near the center under the web, do result in rail fractures, and as nearly as the speaker could determine, about 40 per cent of the rail failures in this country have on the average their origin in these deep seams at the base and particularly near the center.

P. H. DUPLEY² in a written discussion called attention to the fact that the adoption of basic open hearth steel for rails had reduced the breakages and failures to a marked extent. The checking of the basic open hearth ingots in blooming is not nearly so frequent as in Bessemer ingots,

and half-moon or crescent shaped brakes have been reduced in the same sections of rails by nearly 50 per cent. Over three decades ago some railroad companies have designed stiffer sections with a better distribution of the metal so as to carry heavier wheel loads with lower unit stress. Service tests in the track demonstrated that with the higher standards of track secured by the stiffer and heavier sections, and under an increase of wheel loads and higher speed, mechanical abrasion of the cross ties under the rail, the disturbance of ballast and roadbed, were less than under the early light rails and lighter wheel loads, and there was also a reduction of rails in service for the tons carried. Of course the rail sections of three decades ago could not be expected to be adequate to meet the present heavier wheel loads, and three to four times the volume of traffic. Weight is but one

FIG. 7. PIECE OF RAIL BROKEN UNDER THE DROP PRESS

element of steel rails and it must be distributed so that the combined mechanical and physical properties resulting from a good design, and the metal will be capable of not only meeting the intensities of the wheel contact pressure, but also carry and distribute their wheel loads to the frequent supporting cross-ties, ballast and road-bed.

The type of rail section for an economic and efficient engineering structure, must have the metal distributed in sufficient width of head to maintain large wheel contacts and moderate intensity of pressure on the bearing surface of the head. It is a misconception of the relations of the wheel contacts on the bearing surface of the rail heads to assume that as the wheel loads have increased the areas of the contacts between each have been reduced by the recent coming and shape of the wheel tread contours. The Pennsylvania Railroad Company has made their new 125 lb. rail for trial with a 3-in. wide head, while the New York Central and the

¹ Eng. of Tests, Rail Committee, Am. Ry. Engrg. Assoc., Chicago.
² Consulting Eng., Grand Central Terminal, New York.

Boston & Albany Railroad Companies have each used a rail head 3 in. wide for twenty-two and twenty-three years respectively.

Consumers of rails hope that soon there will be installed less injurious methods of straightening the rails of stiffer sections than those now in use. Deep ragging of the blooming rolls must also be considered, for it has been found that where rails are rolled with lighter passes and diagonal rough-

inate the slight defects in their products, so that they will meet all of the exacting conditions of present service.

THE AUTHOR in conclusion said that he fully agreed in regard to the necessity for making sound ingots. He had not departed from his "old-fashioned" position in regard to that; but as long as sound ingots are not generally made, it is a good thing to try as far as possible to ameliorate their bad effects. This process will not remove deep seams. It will

TOP SURFACE

TOP SURFACE

BOTTOM SURFACE
FIG. 8. UNTREATED RAILBOTTOM SURFACE
FIG. 9. MILLED RAIL

ing, the cracks in the bases of the rails are less than where the drafts in the blooming passes are heavy and their ragging deep.

The writer congratulated Mr. Mathias on the introduction of his "hot miller" as a step in advance in rail manufacture, which is also a proof of the manufacturers' efforts to elim-

inate a certain class of seams which occur in practice however careful the manufacturer may be and it will remove the decarburized skin. This process removes the superficial seams after which, if the inspector still finds defects of this character he knows he has a deep seam and ought to condemn the rail.

CEMENT SESSION

FOLLOWING the custom of previous meetings, the Cement Session was an informal gathering of those interested in cement manufacturing held in the rooms of the Society on the eleventh floor. There were about twenty in attendance. The author, Mr. Porter, illustrated his paper during its presentation with stereopticon views. After the presentation of the paper, the author answered a number of questions and an informal discussion was participated in. There was no stenographer present, however, and the discussion was not made a matter of record.

ELECTRIC DRIVE FOR ECONOMIC OPERATION AND DEVELOPMENT OF CEMENT MILLS

BY J. BENTON PORTER, PHILADELPHIA, PA.

Member of the Society

Electricity was first used only for lighting in cement plants; next it was employed to drive machinery located in inconvenient places; then it was used for driving the auxiliary apparatus, and it later enabled the manufacturer to locate this auxiliary apparatus more conveniently; next it provided more flexibility and greater output from the kilns; and finally, electrically is being universally adopted for the entire plant. The last five plants put into operation have installed individual motor drive and five other plants have changed to the electrical drive during the last two years.

A review of the reasons for this growth in the application of electricity to the manufacture of cement will be interesting:

- a It enables the manufacturer to purchase power from central stations, thereby eliminating one of the greatest cost fluctuations from the cost of manufacturing cement.
- b It gives a greater flexibility, permitting economical operation under varying conditions of output.
- c It keeps the driven machine nearer to a predetermined speed, thereby increasing the output and maintaining the quality. As an example, one plant increased its output over 6 per cent by improving its speed regulation.
- d The first cost and maintenance are no longer a nightmare to the management, as years of practical experience have shown that the advantages obtained have justified the cost and that the maintenance compared very favorably with the balance of the equipment.
- e The electric drive has largely eliminated the human element, necessary in making reports, and automatically keeps a record of the power consumed in a plant with an accuracy that cannot be attempted with the mechanical drive.

Only a few managers have realized, or utilized one of the most contributory factors, namely, the various records that electricity can give. This paper is presented in order to call attention more strongly to the value of this salient attribute of electricity, by showing some of the records already compiled, and suggesting some of its future potentialities.

If it were possible to save one cent for every barrel of cement manufactured, how much money would a manager be justified in spending to obtain such an improvement? In a plant turning out 1000 barrels a day, the saving would amount to about \$3600.00 a year, and such a plant would be justified in borrowing about \$20,000.00 in order to accomplish such a saving. Similarly, a 5000 barrel plant could afford to expend about \$100,000.00.

The manufacturer has already inaugurated different systems to find out where the weak points are in his process, but he has been badly handicapped, for he has had to base his records on reports that are not wholly accurate. The assumption that all his mills are running at their maximum capacity as long as they are in operation has to a very great extent been the ground plan; but accurate tests taken on any one machine show that it is almost impossible to keep a mill at a constant load and output, even when meters are installed and the feed regulated to keep the meter needle at a predetermined point.

The advantage of eliminating variables from the manufacturing of cement is apparent when we realize the variations in coal and the variables also shown in the manufacture of steam, which varies in evaporation from 4 lb. of water up to 10 lb. for each lb. of coal. It has also been pointed out clearly that in the production of power from this steam where the consumption may vary from 30 lb. down to 12½ lb. and even lower; and even condensers vary depending on the volume and temperature of the water. These variables, as far as records have shown in cement manufacture, are by far the greatest.

The standard forms of contracts for the sale of power supplied by central stations call attention very strongly to the fact that the customer can purchase power more advantageously if his load factor is kept high. This means that if the daily readings of power required for the operations of the plant were plotted into a curve, this curve should come as near as possible to a *straight line*, since this condition would result in

Abstract of paper presented at the Annual Meeting, December 1914. Complete paper may be obtained without discussion, price 5 cents to members; 10 cents to non-members.

many intrinsic advantages both to the customer and producer of power.

Fig. 1 shows readings taken of the power consumption in an electrically driven plant. The line *B* gives the average of these readings. The line *C* is determined by taking the total kilowatts consumed during the entire 24 hours and dividing this total by 24; and

FIG. 1 POWER READINGS FROM ELECTRICALLY-DRIVEN PLANT

is, therefore, the only accurate record of the power consumed.

It is impossible to obtain a line like *C* from a mechanically driven plant and the difference between the lines *B* and *C* shows the possibility of error, even in the best records of the mechanically driven plant. In the latter, the basis for figuring the cost of power for the entire year has been periodical readings of indicator cards, and these have also been used to determine the amount of power it took in that particular plant to produce a barrel of cement.

The above calculations are based on the assumption that the power required to produce a barrel of cement is always constant, but this is absolutely incorrect. Fig. 2 shows the kilowatts consumed to produce a barrel of cement over a period of 31 consecutive days, and from this curve it is almost impossible to find two consecutive days where the ratio is constant. Thus it is not fair to compare the mechanical drive with the electric drive either in the cost of power or in the amount of power required to produce a barrel of cement.

Continuous operation has been and always must be the watchword for the cement manager. In addition to this he has always striven to run his machines at

their maximum capacity. In other words, he has tried to keep his load constant and at the highest possible average, which, if illustrated by a curve, should show a *straight line*. From curves showing the power taken in different departments each day and over a period of an entire month, those that show the greatest variation from the average *straight line* are indicated, which are the departments that require the greatest study in order to bring them into the closest possible relation to the *straight line*.

By the installation of the individual motor drive, the separation of the various departments in the daily reports and the compilation of these records systematically arranged, the plant manager has a report which enables him to place his finger on any loose ends and even to anticipate where trouble may arise; to trace out an individual machine that is causing an over-demand of power, and after investigation to correct the trouble.

Records taken from tests of power taken in different departments will exhibit clearly an outline of the foundation of plans for improvement. The "Automatic Superintendent," which is to be used only as a base, enables the manager to make wonderful im-

FIG. 2 KILOWATTS PER BARREL, CONSECUTIVE RUN

provements, as it shows him where the improvements are most needed. No one can predict how great are the improvements that can be effected in the efficiency of cement manufacture. There is no general law that can be laid down for any particular class of mills, as the varied conditions of installation and the raw materials are so entirely different.

MISCELLANEOUS PAPERS

THE Friday morning session of the Annual Meeting, December 4, was devoted to a number of papers upon miscellaneous subjects as follows: A Rate-Flow Meter, by H. C. Hayes; Laboratory for Testing and Investigating Liquid Flow Meters of Large Capacity, by W. S. Gile; A New Volume Regulator for Air Compressors, by Ragnar Wikander; Physical Losses of Methane Gas, by P. F. Walker; The Clinkering of Coal, by Lionel S. A RATE-FLOW METER

BY H. C. HAYES, SWARTHMORE, PA.

Non-Member

The velocity with which a fluid flows through a conduit can be determined by finding either its kinetic energy or its change in potential energy with respect to the direction of flow.

In the equation

$$H = \frac{V^2}{2g}$$

where V is the velocity of the fluid and g is the acceleration due to gravity.

The value of H is determined experimentally as the height the fluid is raised by the impact pressure. The pitot tube operates in accordance with this formula, and an application of the formula leads to Thompson's formula

FIG. 1. SECTION OF CONDUIT OF NON-UNIFORM CROSS-SECTIONS

$$Q = K\sqrt{H} \text{ or } Q = K\sqrt{H^3}$$

where Q is the quantity which flows in one second through a V-shaped weir, K is a factor of proportionality, and H is the height of the water level above the bottom of the notch.

The relation between the velocity of the moving fluid and the change of pressure with respect to the direction of flow is obtained through Newton's Law of Motion, mass times acceleration equals the accelerating force.

In Fig. 1 consider the small element of volume ds^3

¹ Prof. of Physics, Swarthmore College. The experiments were conducted at Harvard University, where Dr. Hayes was formerly connected with the Jefferson Physical Laboratory.

Abstract of paper and discussion presented at the Annual Meeting, December 1914. Complete paper may be obtained without discussion; price 10 cents to members; 20 cents to non-members.

of the moving fluid having the front and rear faces perpendicular to the direction of flow. Let ρ be the density of the fluid supposed to be incompressible. Then from Newton's Law we have:

$$\rho \cdot ds^3 \cdot a = dp \cdot ds^2$$

where dp is the pressure difference at the front and rear faces. This simplifies to:

$$\rho a = \frac{dp}{ds}$$

FIG. 2. CONDUIT BENT IN ARC OF A CIRCLE

Putting for a its equal $\frac{dV}{dt}$, and for ds its equal $V \cdot dt$, we get the following relation

$$V \cdot dV = \frac{1}{\rho} dp$$

Integrating this equation between the points 1 and 2 gives

$$\frac{\rho}{2} (V_1^2 - V_2^2) = P_1 - P_2$$

which states that the gain in kinetic energy is equal to the loss of potential energy.

Calling A_1 and A_2 the cross-section of the conduit at the points 1 and 2 respectively, we get through the law of continuity the relation

$$A_1 V_1 = A_2 V_2$$

This enables us to express V_2 in terms of V_1 and the equation becomes

$$\frac{\rho}{2} \left(A_1^2 V_1^2 - A_2^2 V_2^2 \right) = P_1 - P_2$$

By expressing the pressure difference in terms of head and the cross-sections in terms of diameter the equation simplifies to

$$H = \frac{V_1^2}{2g} \left(\frac{D_1^3}{D_2^3} - 1 \right)$$

The venturi meter operates in accordance with this equation.

A trustworthy feedwater record is now looked upon as a necessity in all up-to-date steam plants, for it gives important information concerning the efficiency of the system. Such a record shows how many pounds of water are evaporated per pound of coal.

The meter described here was designed especially to give records showing such things as rate of evaporation of water per unit of coal, irregularities in boiler feed, leaks and slipping losses.

This meter operates through the relation which exists between the velocity of a moving fluid and the

done in obtaining all the formulae, V will be independent of r and our expression becomes:

$$P_1 - P_2 = \frac{\rho}{g} \cdot \frac{ds^2}{g} \cdot V^2 \int_{r_2}^{r_1} \frac{dr}{r} = \frac{\rho}{g} \cdot \frac{ds^2}{g} \cdot V^2 \log \frac{r_1}{r_2}$$

and in order that P_1 and P_2 shall be the pressure per unit area, ds must equal 1. Making this change and writing $P_1 - P_2$ in terms of head we get the relation

$$H = \frac{V^2}{g} \log \frac{r_1}{r_2} = K V^2$$

and some idea of the value of K can be obtained by expanding $\log \frac{r_1}{r_2}$ in a series, which ultimately gives

$$\frac{D}{r} + \frac{1}{3} \left(\frac{D}{r} \right)^3 + \frac{1}{5} \left(\frac{D}{r} \right)^5$$

where D = diameter of conduit and $r = \frac{1}{2} (r_1 + r_2)$.

If $\frac{D}{r}$ is less than 0.67 all but the first term of the series can be neglected and still leave the formula accurate to within 1 per cent. Giving $\frac{D}{r}$ this value we find that

$$K = 0.021$$

wherefore

$$H = 0.021 V^2$$

A meter of this form works well for measuring large values of V , but is not sensitive enough for feedwater purposes. The factor of proportionality increases as r_2 is made smaller, but the higher terms can no longer be neglected, and when r_2 approaches zero the flow approaches more and more nearly to vortex conditions.

Suppose the conduit is so shaped that a vortex is formed, as shown in Fig. 3. The pressure difference between points 1 and 2 will approximate the value given by a circular vortex of the same cross-section and the value of the circulation corresponding to the velocity, V . The difference in pressure between the center and outside of a circular vortex of radius a is:

$$P_1 - P_2 = \frac{\rho K^2 a^2}{8\pi^2 a^4}$$

where K is the value of the circulation and is here equal to $2\pi aV$. Substituting this value and expressing the pressure difference in terms of head we have:

$$H = 0.5 V^2$$

This result is but a rough approximation for the stream lines are spirals instead of circles, but the formula suggests that a sensitive meter might be constructed along these lines. Such a meter should not be greatly affected by fluctuations in pressure such as are always produced by feedwater pumps, for the inertia of the vortical mass will serve to steady the gage readings much as the flywheel does the motions of an engine.

Distortion of the entering stream lines through faulty connections or elbows placed too near the meter

FIG. 3 CONDUIT SO SHAPED THAT A VORTEX IS FORMED IN THE MOVING FLUID

change of pressure in a direction perpendicular to the direction of flow. The pressure gradient in this direction is, of course, zero unless the flow lines are distorted. When these lines are made to describe the arc of a circle the relation is simple.

Suppose, in accordance with Fig. 2, the conduit is bent in a circular arc of outside radius r_1 and inside radius r_2 . A difference in pressure will exist between points 1 and 2 due to the centrifugal force. A small mass dM at a distance r will give an increment of pressure dP outward along the radius such that:

$$dP = \frac{dM \cdot V^2}{g \cdot r}$$

The difference in pressure at the points 1 and 2 is given by integrating this expression from r_2 to r_1 ,

$$P_1 - P_2 = \int_{r_2}^{r_1} \frac{dM \cdot V^2}{g r}$$

If the fluid is incompressible,

$$dM = \rho \cdot ds^2 \cdot dr$$

and if we neglect the effect of viscosity, as has been

will affect the readings but little as these distortions will become straightened in the vortex before the pressure terminals are reached. Finally, the sensitiveness of the meter can be changed by moving the low-pressure vent along a radius of the vortex and as a result the meter could possibly be made to give correct results for any particular temperature by setting the low-pressure vent properly.

This will be possible if the percentage correction in H caused by moving the low-pressure vent is independent of the flow; and if the correction so introduced is proportional to the distance the vent is moved, and the correction which is made necessary through change of temperature is proportional to the temperature change, then it follows that the meter can be made self-compensating by causing the low-pressure vent to be moved by an unequal expansion arrangement, providing the required motion is small.

Whether or not these conditions will be fulfilled can be predicted if the vortex is regarded as circular, for which it is shown that the percentage change in H is independent of K and therefore independent of V .

Calling H the change in H caused by moving the low-pressure vent a distance r from the center, we have for the relation between H and r

$$r^2 = \frac{8\pi^2 a^4}{K^2} H$$

a parabolic and not a linear relation. Plotting this equation for different values of V , i.e., for different values of K , we have a family of parabolas, five of which are shown in Fig. 4. The change in H , caused by shifting the central vent a distance Δr , will be

$$\Delta H = \frac{dH}{dr} \cdot \Delta r = \frac{K^2}{4\pi^2 a^4} r \cdot \Delta r$$

and if r is large with respect to Δr the percentage change in r will be small and the change in H will be nearly proportional to the change in r , $\frac{\Delta H}{\Delta r} = \frac{K^2 r}{4\pi^2 a^4}$ a constant practically.

The change in r necessary to correct for temperature will probably be small, comparable to r_1 minus r_2 in the figure, and if the normal position of the low-pressure vent is a distance from the center r_1 , then, as shown in the figure, the relation between r and H for values of r between r_1 and r_2 is nearly linear. Under these conditions we may assume that the correction introduced by changing r is proportional to the change.

It remains to consider whether the error caused by change of temperature is proportional to the temperature change. The error introduced by change of temperature arises from two sources; first, from the resulting change in the density of the liquid and the second, from the change in viscosity. These errors may or may not tend to neutralize one another depending on whether the meter is calibrated to give the flow in terms of weight or volume.

The calibration curve for the meter is

$$H = K V^a$$

and if H is expressed as pressure the equation becomes

$$p = \rho H = \rho K V^a$$

Calling p_c and ρ_c the pressure and density respectively at the calibration temperature, and p_t and ρ_t the corresponding values at some higher temperature t , we have the two equations

$$\begin{aligned} p_c &= \rho_c K V^a \\ p_t &= \rho_t K V^a \end{aligned}$$

and if V , supposed here to be in terms of volume, is the same in each equation we have for the percentage error caused by the change of temperature:

$$\frac{p_t - p_c}{p_c} = \frac{\rho_t - \rho_c}{\rho_c}$$

And if we assume a linear relation between the density and the temperature, which is very nearly true, the error will be proportional to the change in tempera-

FIG. 4 FIVE CURVES OF THE FAMILY $H = K^2 r^2 / 8\pi^2 a^4$

ture. This error will be negative since ρ_t is less than ρ_c , and must be corrected by moving the low-pressure vent toward the center.

If the meter is calibrated for flow in terms of weight we have for the relation between V and W

$$W = k \rho V$$

where k is a factor of proportionality and W is the weight of flow per second. The calibration equation becomes

$$p = \rho K \left(\frac{W}{k \rho} \right)^a$$

and, as above, we have

$$\begin{aligned} p_t &= \rho_t K \left(\frac{W}{k \rho_t} \right)^a = \frac{1}{\rho_t^{a-1}} \frac{K}{k^a} W^a \\ p_c &= \frac{1}{\rho_c^{a-1}} \frac{K}{k^a} W^a \end{aligned}$$

and the percentage error is

$$\frac{p_t - p_c}{p_c} = \frac{\rho_c^{a-1} - \rho_t^{a-1}}{\rho_t^{a-1}}$$

If a has the value 2 as has been predicted, then the error here will also be about proportional to the temperature change, but the error is positive for ρ_t is less than ρ_c , and the error must be compensated for by

moving the low-pressure vent from the center. In either case the error will be about 0.02 per cent per deg. fahr.

The error introduced by change of viscosity can be predicted as follows: It can be shown that H is proportional to the kinetic energy of the vortical mass and we therefore have the relation

$$H = k(E - D)$$

where E is the kinetic energy, this mass would have if the liquid were nonviscous and D is the energy dissipated, changed to heat, as the water passes through the meter. The value of D can be shown to be pro-

FIG. 5 CURVE INDICATING ERROR DUE TO TEMPERATURE CHANGE

portional to μ , the coefficient of viscosity of the liquid. The relation between H and μ is therefore

$$H = A - B\mu$$

and H varies inversely as μ .

The relation between the coefficient of viscosity and the temperature is nearly linear if the temperature does not approach too near to freezing, so in case of feedwater we may assume the linear relation. The error introduced by change of viscosity will be positive and must be compensated for by moving the low-pressure vent away from the center of the vortex. This error will amount to about 0.026 per cent per deg. fahr.

It results that the errors introduced by change of temperature nearly cancel one another if the meter is calibrated to give the flow in terms of volume, becoming -0.02 per cent $+0.026$ per cent, or 0.006 per cent per deg. fahr.; but if the flow is given in terms of weight, as is usually desired in feedwater measurements, the errors will add giving a resulting error of 0.046 per cent per deg. fahr. These expectations have been very nearly met in the operation of two models of somewhat different form.

EXPERIMENTAL RESULTS

Two models of the meter were constructed and tested in various ways.

This meter operates in accordance with the relation connecting the flow and the resulting difference in pressure between the surface and axis of a spiral vortex. The meter is fully as simple as the venturi or pitot forms and possesses several points of superiority. It consists of a cylindrical chamber terminating in a cone at one end and the other end capped, as shown in the accompanying diagram.

The fluid enters through a tangential inlet, thus giving a vortical motion to the contents of the chamber, and leaves through an axial outlet into which the cone terminates. The low-pressure tap is taken out through the center of the top cap and the high-pressure tap through the side of the chamber. It is to be noticed that the meter has no moveable parts and hence nothing to wear and get out of adjustment.

The calibration curve for this meter is much like that given by the venturi and pitot forms being

$$H = K \cdot V^a$$

where a is a constant as is also K , and V and H are the velocity of flow and the meter head respectively. The value of K for the vortex form is about 4 times that for the pitot forms and 3 times that for the venturi meter having diameter ratio of 2:1. The value

FIG. 6 TEMPERATURE COMPENSATING DEVICE

of the exponent, a , is 2.20, and for the venturi and pitot forms it is 2. This results in making the vortex meter sensitive and thus applicable to the measurement of low rates of flow such as is met with in feedwater conditions.

Four tests were made at different temperatures to determine the error for which the meter must be corrected. These results are given in Fig. 5. The meter was calibrated at temperature 46 deg. fahr. The percentage correction was determined in each case by dividing the actual flow, as given by weighing the discharge, into the difference between this and the value given by the meter. The curve has these values for the ordinates and temperature fahrenheit for abscisse.

B to spring up and down. When the meter is in operation mercury is forced from *A* to *B* until the difference in level is equal to the meter head *H*, and if the shape of tube *A* is such that the quantity of mercury forced into *B* is proportional to the rate of flow through the meter, then the depression of the arm *B*, due to this weight will be proportional to *V*. This motion can easily be transferred to pen or pointer.

The form of tube *A* depends, of course, on the shape of the calibration curve of the meter and can be found as follows. Let this calibration curve be

$$H = K \cdot V^a \dots \dots \dots [1]$$

and let *h* be the depression of mercury in tube *A* when a given velocity of flow *V* is taking place through the meter. Then if the cross-section of *B* is uniform and we assume that the weight of mercury forced into this arm is proportional to *V*, the depth of the mercury will also be proportional to *V*. Call this factor of proportionality *a*. At the same time the arm *B* has been depressed a distance proportional to *V*. Call this factor of proportionality *b*. Then the meter head *H* is related to these displacements as follows:

$$H = h + aV - bV = h + (a - b) V \dots \dots \dots [2]$$

The quantity of water that has passed the meter during any interval of time will be accurately given by the area underneath that portion of the rate curve corresponding to the interval in question providing the velocity has not, during this interval, fallen below 0.216 ft. per sec.

The quantity of mercury required is comparatively small, being about 200 cu. cm. The restoring force for a small displacement of the pen is great because all the displaced mercury tends to restore equilibrium and not the portion displaced by a float. Moreover, the friction of movable parts is reduced to practically that of pen friction.

DISCUSSION

F. ZIE NEEDEN referred to the loss of head caused by the meter. He thought that the dilatation of the lower part of the experimental meter, shown, was rather sudden and that if the venturi meter should be designed in the same way, with the dilatation as sudden as in this vortex chamber, probably the loss of head would be about the same as in the Hayes' meter. He suggested that the stretching out of the lower part and shaping it more toward the form of the diffusive part of the venturi meter, the result would be better.

Mr. Needen pointed out that the author in his enumeration of devices for the recording of flow, had apparently overlooked one design which, is in a way, similar to his own. He referred to the design of the late Dr. Ansler of Schaffhausen in Switzerland which is known as a plano meter. This apparatus is very little known but one made by Dr. Ansler was tried out in Canada in connection with a venturi meter. It consists of two vessels which are connected by a U-shaped flexible tube, and filled with mercury, fixed to a weighing level. Mr. Needen proceeded then to describe the

device and he pointed out the features which render the recorder more sensitive as the zero rate of flow is approached, suggesting that the application of this principle might further intensify the accuracy of the vortex meter described by the author.

Mr. Needen expressed doubt as to whether the Hayes' meter will in itself record accurately in the neighborhood of zero, as he had noted in checking the curves in the paper that in the vicinity of the zero point the meter does not seem to work exactly proportional to the rate of flow. He pointed out also a practical objection that may be encountered when the meter is arranged for practical use, namely, the question of sediment; he suggested that sediment is liable to accumulate in connection with boilers and that this would alter the real radius of the vortex chamber and thus permit a certain inaccuracy in the meter.

Mr. Needen pointed out also that this form of meter is at a disadvantage in that it is considerably larger in diameter than a venturi tube for the same rate of flow. Also if to be used in connection with high pressure, it might be necessary to make this form of meter a great deal stronger than the venturi tube of the same rated capacity.

A. R. DODGE referred to a point of interest in connection with the formula of the calibration curve [1], which indicates that the loss of head varies as the square of the velocity in accordance with the same formula on other meters, the pitot tube meter and the venturi meter. He questioned if this is so, if the Hayes' meter is not of the same sensitiveness at low flows as the venturi meter or the pitot tube meter; that is, if the size of the instrument will not determine the constant.

Another point to which Mr. Dodge referred was the fact that the drop in pressure on a pitot tube meter is negligible, but that with the Hayes' meter the pressure drop is a considerable item.

CARL SMERLING asked if Mr. Hayes had attempted to measure gasoline with these meters. He pointed out the difficulty of the problem of measuring gasoline correctly in a meter and predicted a big field for a meter of this type if made available for gasoline.

THE AUTHOR, in answer to Mr. Needen, pointed out the original meter, which is the first model he made, and suggested that it was more of the shape to which he referred. He admitted that there was much less loss of head in that model, but he stated that the reason he made the second form was to measure the loss of head which he could not measure on the first one; he did not get enough to measure. He said his desire had been to obtain enough loss of head to be able to measure it and also to get the stream lines coming out straight. He told how he had changed the form of meters since then including some changes in the neck, and that the loss of head had been materially reduced.

In reply to Mr. Dodge, he said that apparently the sensitiveness of the vortex meter is almost independent of the size of the chamber. While theoretically it would be absolutely independent, viscosity comes in and makes a little change, but that a large vortex chamber or a small one could be used and the constant would be almost the same. He replied to Mr. Smerling that the meter has been used for gasoline.

LABORATORY FOR INVESTIGATING AND TESTING LIQUID FLOW METERS OF LARGE CAPACITY

BY W. S. GIELE, PHILADELPHIA, PA.

Junior Member

The laboratory described in this paper was designed and built¹ to facilitate the testing and standardization of liquid flow meters of the V-notch weir and other types.

As made by the company at whose plant the testing laboratory was erected, the V-notch meter is combined with a feed water heater of the open type and is provided with an autographic recording and integrating device. A float resting upon the surface of the water in the approach chamber bears a vertical stem, actuating (by means of a cable and drum) a revoluble cam, adapted to displace a pen carriage or integrating train equal distances for equal increments in the rate of flow. The cam embodies the relation between the rate of flow and the head of water on the notch and the adaptation to different rates of flow is accomplished by varying the diameter of the drum upon which the cable winds and the angle of the notch itself, thus making it necessary to establish the relation between the coefficient of the notch and the angle.

The rate of flow through a flow meter may be computed by measuring, either gravimetrically or volumetrically, the quantities discharged during a known period. Such a method, however, involves starting and stopping errors, errors in maintaining the rate of flow constant for the whole period of test, in keeping a record of the exact variations of head or pressure, and in obtaining exact time readings on short runs.

To eliminate the errors involved in the above method, a continuous flow method of test was decided upon. A master flow meter was constructed and installed and so arranged that the rate of flow could be maintained accurately at any desired value for long periods. The performance of this standard was determined with all possible precision, after which it was used to measure the flow through the meters under test. A degree of accuracy could be secured, in the meters tested, practically equal to that of the standard. Also, the latter having once been accurately calibrated, disturbing influences arising from effect of proportions of channel of approach, conditions of surfaces, form and material of notch, directions and interference of currents of flow in the channel of approach, etc., could be ignored.

By the method used, not only is the accuracy of in-

dividual tests assured, but it is possible to conduct a very much larger number of tests and thus confirm the work done and take advantage of the law of averages.

DESCRIPTION OF APPARATUS

The testing plant has a large sump or storage tank from which the water is drawn and elevated to a constant head supply tank at the highest level, as shown in Figs. 1 and 2.

The purpose of the constant head tank is to supply water to a discharge orifice at a constant head so that

FIG. 1. METER TESTING PLANT

the rate of flow through the standard notch may be maintained invariable at any desired capacity.

From the constant-head tank, the water passes to the standard-notch tank, thence over the calibrated standard notch into the meter under test, whence it is discharged to the storage tank to circulate again.

The two volumetric measuring tanks, shown in Fig. 2, were used in the preliminary work of calibrating the standard notch, and afterwards served as catch basins for the water discharged by the meters under test. The capacity of these tanks is approximately 525 cu. ft. each.

The entire plant was constructed with the utmost regard to permanency and rigidity. The foundation consists of a concrete slab carried to solid clay soil and reinforced in all directions by 1-in. rods.

¹ At the Harrison Safety Boiler Works, Philadelphia, Pa.

Abstract of paper and discussion presented at the Annual Meeting, December, 1914. Complete paper may be obtained without discussion; price 10 cents to members; 20 cents to non-members.

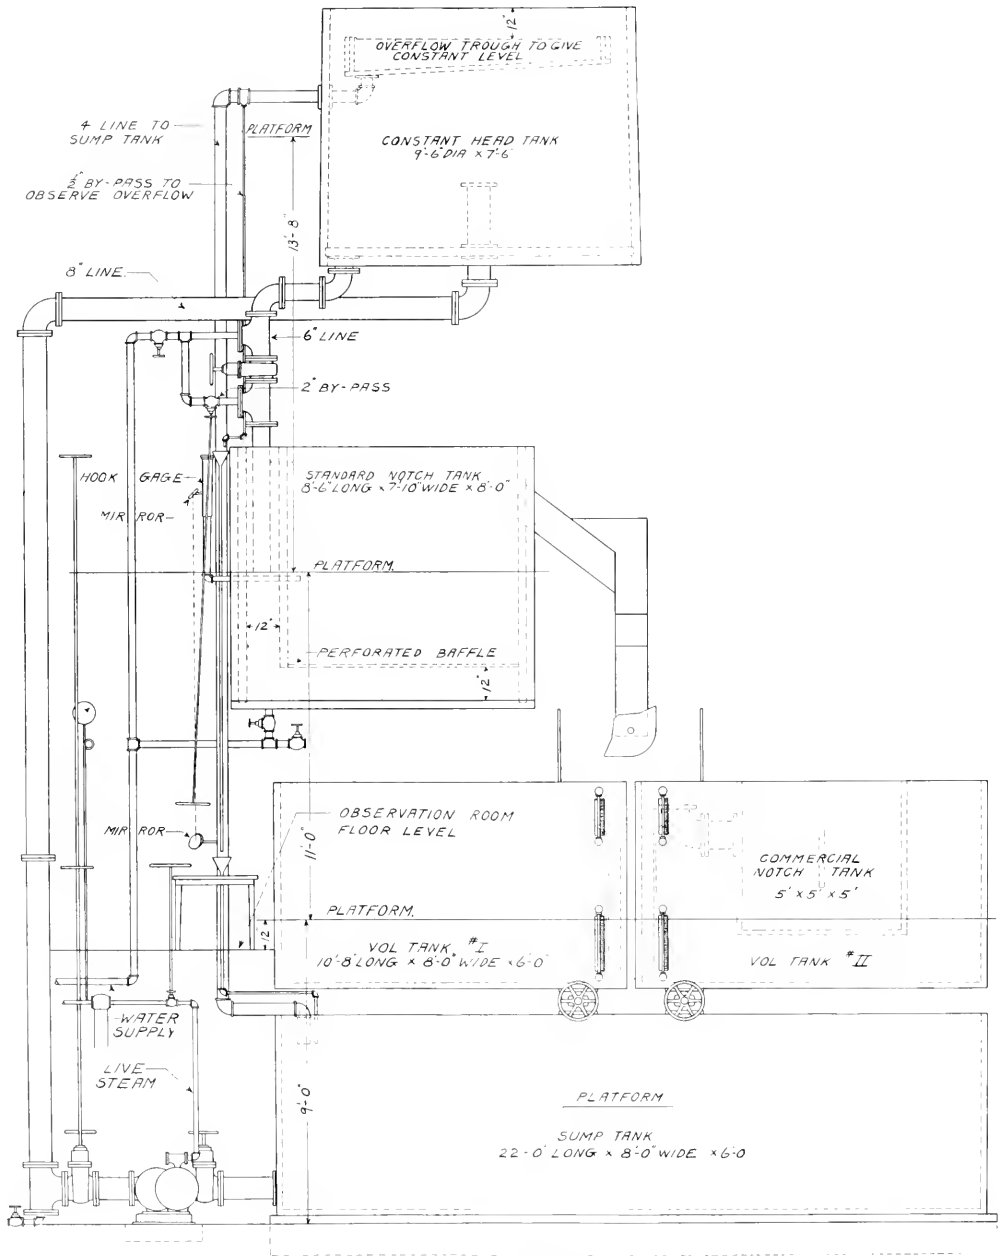

FIG. 2. DIAGRAM OF METER TESTING PLANT

The storage tank rests directly on the concrete foundation and holds a little over 1000 cu. ft. of water. The pump connection is located above the bottom of the tank to prevent sludge being drawn into the pump. The tank is supplied with a drain and washout, and with a system of steam pipes whereby the water may be heated to any desired temperature.

The pumping unit is an 7-in. DeLaval single-stage centrifugal pump. It is gear-driven by a single-stage DeLaval steam turbine, and its capacity is about 120 cu. ft. per minute against the head of the highest tank, which corresponds to a flow of about 450,000 lb. per hr.

The constant head tank is supported on a grill of structural steel carried by rigidly braced heavy columns resting on one of the volumetric measuring tanks. A constant head is maintained in this tank by means of an overflow weir at the surface of the water in the tank. This weir consists of a rectangular trough having inflow edges or weirs on both sides constructed of metal. An overflow is maintained over these edges throughout all experiments and is carried back to the storage tank, the line being provided with a bypass discharging into open funnels on both the standard notch level and the observation room level so that the observer may constantly watch the overflow. The approximate amount of water in the constant-head tank is indicated by a float to which is attached a chain passing over sheaves and extending to the pump room with pointers at each level.

The pipe line from the constant head tank to the standard notch tank contains a 6-in. valve for roughly setting the larger flows and a 2-in. by-pass valve carried around the larger valve for fine adjustment of flow.

The standard notch tank was rigidly constructed and is supported on columns carried outside the volumetric measuring and storage tanks directly to the foundations, the column loads being distributed on the foundation by two 15-in. I-beams grouted in. The tank is divided into two compartments by a rigid partition. The supply line discharges behind this partition 2 ft. below the surface of the water. The water spreads out over the bottom of the tank and rises through a perforated baffle, resulting in a quiet surface of approach for the standard notch.

The standard V-notch, Fig. 3, is approximately 22½-in. high by 11¼-in. wide at the top. Its full capacity at 18¼-in. head is roughly 110 cu. ft. per minute. Owing to the method of calibration, it was not necessary to find the apex or zero level of the notch with extreme precision, only to provide a reference point immovable with respect to the notch itself from which measurements could always be taken.

In order to detect any possible deflection of the standard notch tank due to the weight of water carried, four special gages are provided at each of the

four corners of the tank. The geometrical center of the four positions was located and exactly symmetrical pipe connections were carried from each gage to a common opening at this center.

The level of the water flowing through the standard notch is obtained by means of a specially designed hook gage connecting with the still-water chamber. The unusual construction of this hook gage arises chiefly from the extreme range of height which it must cover and the consequent possibilities of error resulting from differences in temperature both between its

FIG. 3 STANDARD V-NOTCH USED IN TESTING PLANT

various parts and between the water column within the gage tube and the water in the still-water chamber. To eliminate the former, the gage elements are so constructed that expansions due to increased temperature tend to compensate each other, and to eliminate the latter, the hook gage tube is jacketed by flowing water taken from the same source of supply as that to the still-water chamber. The hook gage is shown in Fig. 4.

The hook gage system is aligned by gravity, and prevented from rotation by loosely fitting guides. The hook rod is suspended on a phosphor bronze cable which passes over a very accurate sheave running on a hardened axle. From the sheave the cable passes over a drum on the same shaft with the graduated wheel by means of which the settings are made and the readings taken. This wheel is 18 in. in diameter, and its circumference is graduated in units, each rep-

representing 0.02 in. It has been entirely feasible with these graduations to estimate a movement of 0.0025 in. of the hook.

The register of the point of the hook with the surface of the water is observed from below the water surface, in which position it is possible to see both the hook itself and the reflected image on the surface of the water. The reading is taken through a magnifying lens and reflected downward and horizontally

FIG. 4. DIAGRAM OF HOOK GAGE AND COLUMN

to the observation station, at which point a four-power binocular is rigidly supported for observation of the image. Optical distortion is eliminated owing to the reduction of illumination incident to this magnification. The hook itself is illuminated by means of a frosted incandescent bulb.

After passing the standard notch, the water is guided into a large funnel and conducted to a tipple by means of which it may be directed into either of the two volumetric measuring tanks, or into a meter under test. The tipple is arranged with electrical contacts to ring a gong when it is thrown over to facilitate the taking of time readings.

Owing to the number of readings to be taken and the amount of space covered by the plant, special means are necessary to bring all observations and controls to a central observation room. Fig. 5 shows this room and the desk from which observations are taken, as well as the binoculars and system of mirrors by which a magnified image of either the hook gages on the meter under test, or the hook gage on the standard-notch tank may be observed. It also shows the means for observing the level of the water in the constant-head tank, the overflow from the constant-head tank, the steam pressure in the steam line to the turbine and in the turbine nozzle chamber, from the operator's station: and how the steam throttle of pump, discharge valve and by-pass valve controlling the rate of flow from the constant-head tank to the standard-notch tank are all within the reach of the operator.

POSSIBLE ERRORS—TYPICAL TESTS

In the part of the paper which follows, an idea of the accuracy of the work is conveyed by assuming conditions very much worse than occur in operation and calculating the resultant error.

For instance, if the pump can be controlled only within a variation of discharge rate of, say, 166.8 cu. ft. per hour, and if the head of water over the overflow weir in the constant head tank is 0.2 in. (corresponding to an overflow of 7.26 cu. ft. per minute) an increase in the delivery rate of the pump of 166.8 cu. ft. per hour increases the overflow head to 0.245 in. This increased overflow would increase the head to the valves through which water is admitted to the standard notch tank (which is 10 ft.) from 10.0166 to 10.0204 ft., and the variation would be as the square roots of these two heads, or not more than 0.015 per cent.

The effects of error in the various elements of the hook gage are analyzed in the paper. While with the water jacket described, it was never possible to detect a difference in temperature between the water in the hook gage tube and in the still-water chamber exceeding $\frac{1}{2}$ deg. Fahr. during the course of a whole day, it is interesting to note the results which might be obtained from an unjacketed gage. Without the jacket water, it was found that a difference of 20 deg. Fahr. (from 50 deg. to 70 deg.) was entirely possible and affected a vertical head of 30 in. of water. The reading of the gage under such conditions would be 0.048 in. in error. Fig. 6 shows the percentage error in flow due to error of 0.005 in. in hook gage reading.

The paper concludes with a description of the methods used in calibrating the apparatus and outlines the procedure in conducting a typical test.

The method of conducting typical meter tests in this laboratory is to set the meter into one of the volumetric measuring tanks so that it will receive its

supply from the standard notch and so that the volumetric measuring tank will catch its discharge simply as a catch basin and return it to the storage tank. The head of the standard notch, corresponding to the desired rate of flow for which is desired to find the head in the meter under test, is read from the larger scale curve and the hook gage on the standard-notch tank accordingly set. The flow through the system is then brought to the desired rate by controlling the water level in the standard-notch tank to the point of its hook gage. When conditions have become stable the head over the notch under test is read by means of its hook gage.

In running tests, it is necessary only to observe that the water level remains at the point of the gage on the standard notch and it is not necessary to read the height of the hook gage on the standard-notch tank during the progress of an experiment. The hook gage applied to the meter under test is provided with an extended shaft, bringing the graduated scale to the observation room where the operator can read the height of water passing over the weir under test. This reading is taken immediately above the eye pieces of the binoculars through which is observed the coincidence of the water surface and the hook.

DISCUSSION

H. E. EHLERS asked whether any experiments were made to determine how much variation existed in the surface of the water in the V-notch tank. He said the quantity flowing over the notch is determined by the hydraulic head back of the notch, and while it may be entirely possible to measure the level in the hook gage to an accuracy of 5/1000 in., he would like to know how nearly uniform the water level in the tank itself remained.

He referred to the assumed error of measurement of the head in the two large standardization tanks of 3,100 per cent at the higher rates of flow. The maximum flow is about 110 cu. ft. per minute, which allows about 5 minutes only for the filling of one of these large tanks. He asked how still the surface of the water in these tanks became. He said his own experience had been that water flowing into tanks under such conditions causes disturbances and pulsations which take a considerable time to die out. The surface may become smooth but it continues to rise and fall or pulsate.

Most of these meters, he said, are used for metering hot water, and the statement is made that the storage tank is provided with a system of steam pipes for heating the water to any desired temperature. A meter of this type measures volume, which is converted to weight by a direct coefficient. The weir is calibrated at 70 deg. or ordinary temperatures and a cam is worked out which is intended to give a rating in pounds. If the temperature of the water is raised to say 210 deg., its density is changed and so is the depth of immersion of the flow used to indicate the head of the weir. The first change is constant, but the second change is a variable and also has a much greater effect at low heads than it does at high heads. He asked

how these weirs are calibrated for temperatures as high as 210 deg.

GEORGE H. GIBSON contributed a written discussion of which the following is a summary:

Two considerations favor the general adoption of the V-notch as a boiler feed meter. The first is its sensitiveness at small flows and the second its simplified construction made possible by assuming that the rate of flow is proportional to the 5/2 power of the head. This law is not strictly true even under ideal conditions, but its assump-

FIG. 5 OBSERVATION ROOM

tion facilitates the construction of float-actuated cams to move the recording pens.

The numerous combinations of different notches with weir chambers of various dimensions required such a number of calibrations as to render volumetric and gravimetric methods tedious as well as expensive. To obviate this, the elaborate testing plant described was constructed and by its means the manufacture of V-notch meter chambers has been standardized.

In answer to Prof. Ehlers, Mr. Gibson said that the sensitiveness of these meters at small flows is not a matter of the operation of the notch itself. Overcoming the friction of the translating cam consumes such a large fraction of the power available for operating the recorder as to render impossible the measurement of differences in head at these flows to great accuracy. This is particularly true

in the case of the venturi meter in which reducing the flows to $\frac{1}{4}$ reduces the velocity head to 1/16; below this flow great accuracy with this meter is out of the question.

J. H. Morgan gave some personal experiences in a manufacturer's water meter testing plant regarding the difference in level in the filling tanks. The weir in this plant is flat-crested and is 8 ft. in width. When running at approximately a foot head, the differences of level in the weir chamber is not more than 2-100 ft. provided the stream is properly baffled as it enters the chamber. The constant head is obtained by a centrifugal pump driven by an electric motor, the differences in head being obtained by varying the speed of the motor. In a pressure chamber into which the pump delivers, the differences in head caused by the vibrations due to the action of the pump register from 1/10 ft. to 5-100 ft.

FIG. 6 CURVE SHOWING PERCENTAGE ERROR IN FLOW DUE TO ERROR OF 0.005 IN. IN HOOK GAGE READING

THE AUTHOR in replying to Prof. Ehlers said that the relative error at various heads due to the same error in reading the head, or what corresponds to the same thing, the error between float and can in various positions, is shown in Fig. 6. The correct method to compensate for this error is believed to be by measuring the force required to move the recorder and then to so proportion the water line area of the float that the latter will displace an amount of water proportional to this force. In this way it is possible to take full advantage of the greater relative accuracy of the V-notch at small rates of flow. Considerable trouble was experienced in getting the surface of the water in the standardization tank and in the volumetric tank quiet, but disturbances in these tanks are now controlled even with the rapid passage of water. Variations in the surface of the water in these tanks were shown by the gages in their corners.

He said that most of the other points raised by Prof. Ehlers had been covered by Mr. Gibson.

In a V-notch meter there are so many variables, each affecting the other, that it seems best when making commercial meters of this type to build each meter as nearly correct as possible, test it under its working conditions, and make the results of this test standard for that meter.

A NEW VOLUME REGULATOR FOR AIR COMPRESSORS

BY RAGNAR WIKANDER, PITTSBURGH, PA.

Non-Member.

The variation in the consumption of compressed air being delivered by an air compressor necessitates some means of regulating the delivery in order to keep the receiver pressure as nearly constant as possible.

A number of regulators, governors or unloaders have been designed for this purpose and the object of this paper is to describe a new method serving the same purpose in a simple and efficient manner.

The existing volume regulators and their limitations and shortcomings which have led to the development of this new device are first reviewed, as follows:

A simple method for regulating the intake air is to vary the speed in proportion to the air consumption. For compressors driven by duplex or cross-compound steam ends this method is used to great advantage, the speed variation being, as a rule, obtained by means of a "speed and pressure governor," which acts upon a valve throttling the inlet steam. For compressors driven by single or tandem compound steam ends this method proves less advantageous, because the speed cannot be reduced below a certain value without excessive reduction of the flywheel effect.

A similar regulation between certain limits can be obtained by starting and stopping the compressor as soon as the air in the receiver pressure sinks below or rises above certain values. This method is suitable for small motor-driven compressors, but for larger motor-driven compressors it is, as a rule, not advantageous. In all cases, frequent startings of an air compressor under load are very hard on the transmission organs. In cases of belt-driven compressors, a belt shifter, automatically operated by air pressure, is sometimes used with a tight and loose pulley.

The choking intake unloader is in very common use. It consists of a choking valve placed in the suction pipe of the compressor and influenced by the receiver pressure. The advantages of this unloader are simplicity and gradual operation. Its disadvantages are waste of power, carbonization of the lubricant due to the great heat generated in the compressor cylinder when working on partial load, and the danger of explosion produced by such carbonization. If the unloader is arranged to open or close the intake entirely, the gradual unloading is sacrificed but the loss of power is avoided. The fact that this unloader is in common use, in spite of these great drawbacks, shows the need of a good and simple volume regulator.

¹Hall Steam Pump Co., 918 St. James St.

Abstract of paper and discussion presented at the Annual Meeting, December 1914. Complete paper may be obtained without discussion; price 10 cents to members; 20 cents to non-members.

Regulation can be secured by variation of the cylinder clearance. This method is distinctly superior to the choking inlet method. In a well-known application, two clearance pockets are provided in each end of each cylinder, and automatically operated valves put one or more of these pockets in communication with the cylinder. The receiver pressure controls these various valves so as to regulate the volume of air pumped. The drawbacks of this system are high cost, extra space required, complication and limited number of efficient capacities of the compressor.

A fourth method of regulation is by keeping either the suction or the discharge valves open by force. If the former, some of the air drawn from the suction pipe during the suction stroke will return to it during the discharge stroke. If the latter, compressed air will enter the cylinder during the suction stroke and keep the suction valves closed, allowing no intake air to enter the cylinder. The first method is in common use all over the world, and it is possible to reduce the capacity of the compressor to one-half by keeping the suction valves at one end open by force all the time. The objections to this system are again high cost, complication of parts and the limited number of efficient capacities.

The best known type of unloaders on piston type compressors with positively moved valves operate to hold the suction valves completely open for a short time as soon as the air pressure exceeds the desired limit, and permit them to operate normally as soon as the pressure sinks. Several systems are, however, in use in which positively moved valves connect the cylinder with the suction pipe during a shorter or longer part of each discharge stroke. Both these systems operate satisfactorily and their only drawbacks are to be found in the high cost and rather complicated mechanisms required.

The object of the new regulator, which is called the Hall Volume Regulator, is to provide (in case of a piston-type air compressor with poppet valves) a simple, efficient and inexpensive means of varying the amount of intake air to correspond with the amount of compressed air being consumed.

The principle of the device is as follows: If the suction valve is held open by force after the suction stroke is completed, then on the discharge stroke a pressure is developed in the cylinder tending to overcome this force and close the valve. By a very gradual regulation of the force holding this valve open, its closing at an adjustable point of the discharge stroke is obtained.

The regulator is shown in Fig. 1. *A* is the compressor cylinder. *B* is the suction valve provided with a spring tending to close it. *C* is a piston, the action of pressure on which is to tend to hold the suction valve open. *D* is an auxiliary tank connected with the main receiver *F* through a port *G*, and with the

atmosphere through the leak *E*. *H* is a pilot valve which closes the port *G* when the force exerted by an adjustable spring on the valve piston *I* overcomes the air pressure on its bottom. *J* is an adjustable needle valve which can be set to obtain a constant leak from the main to the auxiliary reservoir, thereby preventing the pressure in the latter from decreasing below a certain value.

When the compressor is working at a constant partial load, the pressure on the piston *C* is kept practically constant by admitting through the valve *H*

FIG. 1. APPLICATION OF REGULATOR TO AN ORDINARY POPPET VALVE AIR COMPRESSOR, SHOWING REGULATION BY ACTION ON THE SUCTION VALVES.

into the tank *D* an amount of air equal to that escaping through the leak *E*. The suction valve then closes at such a point of the discharge stroke as to compress exactly the quantity of air consumed, the pressure in the main tank remaining constant.

An increase (or decrease) in the consumption of air will cause a slight momentary decrease (or increase) of the pressure in the main tank and of the quantity entering the auxiliary tank. This will decrease or increase the pressure in the auxiliary tank and change the cut-off of the suction valves so as to increase or decrease the amount of intake air until new conditions of equal supply and consumption are established.

The object of the valve *J* is to admit constantly so much air to the auxiliary tank as will cause the compressor to work at its maximum capacity for which a certain pressure in the auxiliary tank is necessary. If more air is admitted, the capacity of the compressor is reduced.

The same principle can be also applied to the regulation of the discharge valves of a piston inlet type of compressor, when it operates to close this valve at an adjustable point of the suction stroke. This application is described and illustrated in the paper, as is also a method of electrical control of the regulator.

It is claimed that the regulator can be applied with advantage to single or tandem compound steam driven compressors, being easily operated in connection with the ordinary speed and pressure governors. The device is also stated to be especially applicable to gas engine driven air compressors and to natural gas compressors in gas pumping plants where the pressure varies on account of field conditions. A chart is given showing the comparative power consumption and quantity of free gas pumped per minute by a 17-in. cylinder compressor without and 20-in cylinder compressor with the Hall regulator.

The paper concludes with a number of indicator diagrams taken from a standard Hall poppet valve air compressor equipped with this regulator.

DISCUSSION

W. L. SAUNDERS, in a written discussion, stated that he regretted the author had given so little space to the system of clearance unloaders or controllers, which the writer claimed to be not only extremely simple and inexpensive, but had been demonstrated to be highly efficient.

He stated the cardinal requirements for the successful operation of a regulator for high speed compressors operating at constant speed are:

First, underload regulation must be obtained with such a degree of economy that the reduction in power required will be practically in a direct proportion to the reduction in output capacity.

Second, all mechanisms for regulating the compressor must be independent of the running gear of the compressor, otherwise the timing of the regulator as the regulation varies is difficult to accomplish, and the delicate yet durable mechanism required, operating at the full speed of the compressor continuously, is extremely difficult to design and manufacture. The difficulty and cost of maintenance and the shut-downs requisite for repair have proved excessive when the regulating mechanism is part of or dependent upon the running gear of the compressor.

Third, the regulator should be of such design that, when the compressor is called upon for average operation at partial load capacity, it can be so adjusted by hand as to limit the maximum capacity, and thus permit the compressor to operate at a higher average capacity or higher load factor than would otherwise be possible. This is a valuable feature under conditions where electric power service is furnished under a special maximum demand charge.

He stated that with the automatic clearance controller the inlet capacity of the compressor is reduced without reducing the intake pressure. On a two-stage compressor a constant ratio of compression throughout the entire load range, and the highest compression efficiency, is maintained throughout. The reduction in power secured with this method of control is practically in direct proportion to the reduction of load. The regulator is simple in construction and entirely automatic in operation.

On account of its under-load economy, the automatic clearance type is in his opinion of value in the majority of conditions of constant speed power-driven compressor service requiring under-load regulation.

JOSEPH ESHERICK wrote congratulating the author upon his excellent paper and for his work in developing the Hall volume regulator.

In regard to volume regulators, he said the author made no mention of the Richards Pressure Unloader. This unloader permits the compressor to run unloaded until the desired speed is obtained, when it loads the compressor automatically. The device is placed in the discharge line between the compressor and receiver and is simple and inexpensive. It is used primarily on motor-driven compressors. Another type, called the Initial and Pressure Unloader, has been designed for continuous running steam and electric-driven compressors. This embodies means of adjustment for any degree of regulation, from two to fifteen pounds.

One of the chief advantages of the Richards unloaders is that they permit, while the compressor is running unloaded, the passage of free air through the cylinder, with its resultant cooling effect on these parts.

PAUL DISERENS wrote that the author's objection to the choking unloader were well taken as directed against its application by gradual throttling, but that this application was practically obsolete. They were not well taken in the case of the total closure unloader, which is both safe and efficient when properly protected by atmospheric relief valves. The only drawback to the total closure unloader is the sudden change from full load to no load it causes, but where this is not objectionable at the electrical end the device answers very perfectly.

Theoretically the principle of varying the capacity of a compressor at constant speed by changing the clearance (clearance unloaders) is sound. The writer sees, however, the chief objection to the practical application of this principle for volume control in the obstruction to free communication between cylinder and clearance chambers occasioned by the restricted valve openings, of necessity interposed between cylinder and valve pockets.

The author's comment on unloaders on compressors with positively moved valves implies that unloaders operating the suction valves are the best type, whereas one of the most widely used devices of this nature involves an auxiliary bypass valve and connections.

The volume regulator which is the subject of the paper appears to depend on the gradual increase, during the entire length of the compression stroke, of the cylinder pressure as compared with the suction passage pressure, but it does not seem clear why such gradual increase should occur.

It would also appear that on compressors of medium and larger sizes, operating at the relatively high speeds now generally employed, a multiplicity of valves equipped with by-passing control would be needed. This would appear to present some difficulty in synchronizing their action.

The application of the regulator described to a two-stage compressor necessitates the use of two independent governors, one to regulate the line pressure and the other the intercooler pressure. Though this does not constitute a serious objection, it implies a complication to which the author takes exception in other forms of volume control.

JAMES TRIBE expressed his written opinion that the form of valve to which this regulator was shown applied might operate with fair success under low-speed conditions such as formerly obtained, but in modern compressors running at say 150 r.p.m. such a valve must have a very short life. Even the pressed steel cup valve, used for many years by the best builders on account of its lightness, was proving too massive to withstand the shock incident to valve action with high speeds.

An air compressor invented by Mr. G. H. Reynolds in 1876 and disclosed in U. S. Patent 187,906 embodied the principle of by-passing air from the cylinder to the external air on the compression stroke when the receiver pressure was increased above a certain limit. This invention, long since abandoned on account of the changing conditions of practice, was similar to the Hall regulator in that the receiver pressure controlled valves in the cylinder for unloading the compressor automatically.

Several large compressors recently built by the Allis-Chalmers Company have been equipped with unloaders embodying the Reynolds principle but reversed in application. These unloaders are independent of either the inlet or discharge valves and are not influenced by the speed of the machine.

JOHN GLASS¹ contributed a written discussion in which he said the Hall regulator would not apply to a pipe line as to a tank, as it is not practical to carry a constant discharge pressure at the various compressing stations of large gas-pumping plants. In such installations, the gas pressure is partly regulated at the compressing plant closest to the point of consumption, but the other plants back on the line are run at constant speed, that is, compressing all the gas possible. If more pressure is required in the line extra wells are turned in, and if the unloading device is affected by this, shortage of gas will occur at the consumption end.

He thought that this regulator was well adapted to gas engine driven compressors, especially in starting, and also on account of the limited capacity of the gas engine for overload, but that it was not of very great advantage in gas-pumping plants, as the changes in pressure are too great. When the field pressure drops the discharge drops also, giving about the same number of compressions. A large diameter compressor would be a disadvantage as the speed would have to be reduced so as not to exceed the economical number of compressions, about 4.5.

The facility with which the regulator could be applied he considered to be of importance.

¹ Chief Engineer, Carnegie Natural Gas Co., Pittsburgh, Pa.

FRANK RICHARDS said that the device described could only be used in connection with obsolete or obsolescent types of inlet and discharge valves. He said we have learned that poppet valves are by no means the best for air compressors. The poppet valve has considerable inertia, and moreover the resistance of a spring has to be overcome in opening it; oil gums its guides and the valve requires frequent examination and cleaning; it gives a more or less restricted and tortuous passage for the air, and this feature is accentuated when the air has to play back and forth for regulation purposes. With this valve, too, the pressure of the air within the cylinder is necessarily lower at the beginning of the compression stroke than that outside.

The Corliss inlet valve, wide open for nearly the entire stroke, and with large port area and a direct passage for the air into the cylinder, gives a freer inrush to the air and a fuller pressure at the beginning of the compression stroke.

The Rogler valve, which has replaced the poppet valve, annihilates its objectionable features without entailing others. This valve consists of a very thin steel plate covering concentric annular openings in the valve seat, and with a minute, free lift it gives the largest and freest passage for the air that has ever been realized. The Hall regulator cannot be applied to either this or the Corliss valve.

The regulation of a compressor should be accomplished without interference with its ordinary operation, and so it might be well that neither the inlet nor the discharge valves should be interfered with for this purpose. This may be secured by controlled changes of the cylinder clearance, an almost ideal mode of regulating the output from nothing to full delivery. It is possible mechanically to have an automatically pressure-adjusted changeable clearance for the air cylinder so large that at one extreme of its capacity a whole cylindrical of free air shall, when compressed up to receiver pressure, just fill this clearance space and none be expelled to the receiver. Then the compressor could run along continuously, and the air in the cylinder would be alternately compressed and re-expanded and no power expended.

A partial reduction of this clearance space would compel an expulsion or delivery of a portion of the air, and the remainder would re-expand upon the return stroke the same as with the clearance of full capacity, but in the latter case at the end of the stroke a portion of free air would be taken in sufficient to replace the volume delivered, and so on. With this adjustable clearance reduced to its minimum, the cylinder would be delivering its full charge of air, and its action would be entirely normal.

Such a clearance control is not yet fully realized, but the four stage clearance controller already in extensive use gives highly satisfactory results in practice. The only expense it involves is its initial cost, as it requires no constant operating expense.

THE AUTHOR, in his closure, said that although Mr. Richards referred to poppet valves as being obsolete or obsolescent, he was of the opinion that almost 90 per cent of the compressors used in this country were fitted with this type of valve.

In reply to Mr. Glass, who stated that a volume regulator operating with constant pressure was not needed in large gas pumping plants, the regulator described is not limited to constant pressure, as it can also be operated to give any constant volume desired. In the ordinary practice, a gas engine driven compressor is built so small that the engine can pull it under any conditions. With the regulator described, the gas engine can be built just large enough to take care of the ordinary conditions, and the amount of intake gas so regulated that the work required for its compression corresponds to the capacity of the gas engine.

In reference to the criticism by Mr. Tribe of the novelty of this regulator, the author stated that investigation had established the existence of only one prior invention of similar character. This was the subject of a patent to Mr. E. A. Rix in 1900 (U. S. Patent No. 602,170), in which a positively moved system of levers, similar to the Corliss valve gear, operated to close the inlet valves of a compressor at some point of the compression stroke varying with and dependent upon the pressure in the outlet pipe or its connection.

DAMAGES FOR LOSS OF WATER POWER

BY F. W. DEAN, BOSTON, MASS.

Member of the Society

When the water of a stream is diverted at any point, damages for loss of power must usually be paid to any mills having a water power plant located below the point. Cases are frequently heard before a commission, occupy much time, involve considerable expense, and the testimony is widely divergent. Some of the questions about which such testimony differs are discussed in this paper under the heads: Determination of value of water power, rate of capitalization, proper development of water power, method of estimating average yields, proper auxiliary engine to install, kind of coal, economy of steam plants, use of existing engines and boilers to supply loss by diversion, efficiency of water wheels, friction of water wheel gears and shafts, developed and undeveloped powers, and value of water for non-power purposes.

It is now generally understood that the determination of the value of water power takes into consideration the cost of making power by steam which may be spoken of as the standard for comparison. This value is the capitalization of the annual saving by the use of water power. The mill can be operated by the water power combined with a proper steam plant to produce uniform power throughout the year, or by the best adapted steam plant. The costs may be tabulated in a general way as in Table 1. If the amount

Abstract of paper and discussion presented at the Annual Meeting, December 1914. Complete paper may be obtained without discussion, price 5 cents to members; 10 cents to non-members.

of the first column exceeds that of the sum of the second and third, the water power has value.

The theory in a water power damage case is that the award shall be such that the interest thereof shall be sufficient to equal fully the extra expense caused by the diversion. This rate is usually taken at 5 per cent, but is a subject of argument.

In the case of an undeveloped power a higher rate of capitalization may be used as a means of scaling down the value and as representing the necessary profit of an enterprise.

Water powers are seldom developed to the power of the wet months, but to the average power of the eighth or ninth month when the stream flows are arranged in the order of wetness.

A water power produced by the unassisted natural flow of the stream is of very little value when developed to the customary extent since the largest yield in a given period is often many times the smallest yield (Table 2).

Wettest.....	4.776	4.654	7.21

Areas are frequently available in the watersheds that can be dammed and overflowed in the wet months. This is a saving feature of water power development of great importance, but probably in no case results in a uniform power. Table 3 shows the results for the average and dryest years in a case investigated by the author. Even in the smallest development, a steam plant is necessary.

In treating a water power problem, a systematic arrangement of the yields of the stream is necessary and the most convenient and effective one is that of monthly yields in the order of wetness or dryness. The calendar order is without significance.

Investigation shows that the most economical engine to install depends upon the power to be made up to produce a steady power. Between certain limits, the most economical engine is the simple non-condensing

men are employed, but such plants as the latter should not be taken as criterion for basing an award for damages.

Engines and turbines may be non-condensing or condensing, simple or compound. Steam engines high in economy are being devised. Superheated steam is being introduced and may be at any time installed in mills that are damaged by loss of water. Using better condensing apparatus is resulting in improved economy. The simple non-condensing engine, the exhaust steam of which is utilized for mill processes, forms the most economical steam plant, and this is generally understood. These considerations bear upon the testimony that may be given in cases such as are under consideration.

Another feature of damage cases is that of allowing for the variable loads that auxiliary engines carry, but recent engines are not as wasteful with such loads, as were engines made 20 years ago. However this may be, there is considerable uncertainty in estimates of the coal used with variable loads.

It is beneficial if in damage cases the power to be made up month by month is sufficiently small to be assumed by the existing engine in the plant. The main engine is likely to be of an economical type for the work and would in every way be more satisfactory to the damaged party by itself than in connection with an additional engine. If an additional engine is put in, the award will be larger, but the recipient will have a more expensive plant. If the existing engine cannot carry the additional load, another should be added, which is usually done if the highest award is sought.

In many cases, too, the existing boiler plant and force of firemen is ample to carry the additional load. It is better if this is so, but if not, the award should contemplate an addition.

The maximum efficiency of new and clean waterwheels has been found to be nearly 85 per cent. Testimony is often given to the effect that the average efficiency of waterwheels is as much as 80 per cent, and this is used in estimating the power lost, while an examination of efficiency curves, and contemplation of conditions to which wheels are subject, show that such an efficiency under the conditions is impossible. In the author's opinion the average efficiency used in water power damage cases should be taken at not more than 75 per cent.

The power of vertical water wheels is transmitted through bevel gears, the friction of which has been shown to be from 3 to 4 per cent. The shaft of a horizontal waterwheel, and the horizontal shaft driven through the gears of a vertical wheel, correspond with the shaft of an engine, enabling powers to be compared. The delivered power from horizontal shafts for wheels and engines, compared with the steam power is:

type. Simple condensing engines, compound condensing engines, condensing or non-condensing steam turbines, may be best. The greatest net economy as made up of fixed charges and costs of operation must be considered.

The make-up steam powers vary between wide limits, and judgment must be exercised as to the best type of engine to install and also its size.

The kind of coal considered in any case should be the normal coal of district. This is nearly always a bituminous coal, although the coal actually used is often a mixture of bituminous and fine anthracite.

In damage cases a great deal of testimony is given concerning the economy of steam plants. It is well known that the economies of such plants are very variable and differ from each other. In some cases great care is taken to have good plants carefully operated, while in others they are neglected and incompetent

In the case of a developed power the problem of determining a proper award is comparatively definite. In the case of an undeveloped power, supposititious cases have to be assumed, and the award is a guess.

A knowledge of the costs of undeveloped powers is, of course, very valuable, but such information is difficult to obtain.

The determination of the value of water for non-power purposes does not usually come from the diversion of water, for when this occurs it is common to

PHYSICAL LAWS OF METHANE GAS

BY P. F. WALKER, LAWRENCE, KANSAS
Member of the Society

In the recent marked development of the natural gas industry in the Middle West, there has been a realization of the necessity of a greater degree of accuracy in the many technical problems which have arisen.

The compression at various points in the transmission line in order to maintain pressures giving economy in transmission, the determination of conditions of flow by line-flow formulae and the measurement of the gas purchased and sold, involve an exact knowledge of the characteristics and behavior of gas under varying

FIG. 1 PV-VALUES; T-CONSTANT CURVES ON PRESSURE, ORIGINAL DATA. VOLUMES OCCUR IN RELATIVE VALUES ONLY

give a manufacturer as much water as he needs for such purposes, as for boilers, paper washing, dye houses, etc. Sometimes the question arises as to how much shall be paid to the owner of a source of supply for a quantity of water, or how the price shall be readjusted.

DISCUSSION

JAY M. WHITHAM, in a written discussion, expressed the opinion that the range of efficiency of variable loads which have to be allowed for in damage cases, is greater than the author appears to think.

As regards the use of existing engines and boilers to supply power lost by diversion, he thinks that the market value alone must control, and also that the condemning party should pay its pro rata of operating costs in the mill. He emphasizes particularly that in all condemnation of water powers, local considerations must control, and the loss in market value must determine the result.

pressures. Methods of dealing with these problems have been the subject of various recent articles in The Journal, and through this and other channels much has been done towards systematizing the work and establishing formulae for convenient calculation.

In all the published matter available, calculations have been based on the laws of perfect gases. The laws of Boyle and Gay Lussac have been assumed to hold for the gas being transmitted and measured, but it is well known that this is not true.

The present paper attempts to develop a few equations which relate quantities of real significance and to establish values of some coefficients which may be applicable where a very high degree of accuracy is demanded.

The error involved in the use of the perfect gas

Abstract of paper and discussion presented at the Annual Meeting, December, 1914. Complete paper may be obtained without discussion, price 10 cents to members; 20 cents to non-members.

laws is most pronounced in line-flow formulae and in measurement of volume. It is necessary to convert high pressure volumes to equivalent volumes under pressure at or near atmosphere. Density is always determined under atmospheric pressure, or slightly above, and it is then assumed that under widely vary-

equation, $PV^n = \text{constant}$, the usual value taken for n is 1.26. It is to be expected that the true value is different from this, which is of considerable significance since V is comparatively large. The variations from the laws of perfect gases in the case of changing temperature are developed in the paper as a step in the process of investigation, although not commercially important.

Analyses showing the composition of natural gas were published in The Journal in May, 1912. The average shows a content of over 80 per cent methane, while the hydro-carbons closely associated bring the total gas of this general character to over 90 per cent. It is evident therefore that a study of this leading element is of prime importance. Because of the presence of heavier gases, however, natural gas is to be expected to vary from the laws of perfect gas by a still greater amount than does methane, so that the factors determined by an analytical study of the latter represent differences even smaller than should be adopted in practice.

Information bearing upon the physical properties of methane is extremely limited. All that was found were values of pressure and volume under varying temperatures according to the determinations by Amagat, and values for the specific heat by various authorities. In the tables of physical constants by Landolt, Börnstein and Meyerhoffer, specific heat under constant pressure is given as 0.5929 for temperatures varying from 18 to 208 deg. cent. In the same reference, values of 0.5915 at a pressure of 1 atmosphere and 0.6916 at a pressure of 30 atmospheres are authorized by Lussana. With other physical chemists,

the above authorities assign an average value of 1.1315 for the ratio of specific heats at constant pressure and constant volume. The value used here is 1.235 to 1.24. This is given by Mr. Kent. In an appendix the effect of varying temperatures on this value is considered. Another value commonly used by gas men (and in the paper, above referred to

in The Journal, May, 1912) is 1.266.

Fig. 1 is a graphical representation of the PV values for methane (Landolt, Börnstein, Meyerhoffer, Amagat). This shows an appreciable variation from the perfect gas, for which the PV curve would follow a horizontal line.

The specific heat values for constant pressure and constant volume are both expressed in the form $(a + bt)$, the quantity a differing by a fixed amount

FIG. 2 T-CONSTANT CURVES FOR 1 LB. OF GAS. CURVE A' IS A PERFECT GAS ISOTHERMAL. VOLUMES OCCUR IN TRUE SCALE

ing pressures this factor will vary in a fixed proportion to the density of air under widely varying pressure. Since air contains saturated vapors which do not conform to the laws of perfect gases, serious errors may be involved in this assumption, entailing financial loss to handling companies. In many other calculations, the equation expressing the relationship between pressure and volume during the adiabatic change of state becomes of great importance. In the characteristic

for the two cases. It is probable that the values thus given are slightly in error because of this constant difference which represents the work done during a constant pressure change accompanying one degree change in temperature, and the change of volume for such a constant pressure change would be represented by a curve rather than by a straight line. The error involved is, however, extremely small. It should be said, that the uncertainty as to the values of specific heat is a matter of far greater importance in the actual handling of natural gas than it is in connection with a discussion of pure methane. Natural gas carries many other elements, these often being actual particles of liquid, and any attempt to use

With this set of values of PV for pressures of 150 lb. to 2,000 lb., a single constant temperature curve was drawn on an enlarged scale, and the curve was extended to the standard pressure of 14.7 lb. per sq. in. Since the density of methane at this pressure and temperature is well established at 0.04464 lb. per cu. ft., the PV value of 2690 gives 0.05674 lb. of gas for the weight. Knowledge of this weight now made it possible to express the volumes in absolute units. While it is true that the extension of curves outside of the observed values on these preliminary diagrams is subject to some error, the curves thus extended are of very slight curvature and are of a character well established.

FIG. 3 DERIVATION OF ADIABATICS, ALL VALUES FOR 1 LB. OF GAS

measuring devices which involve a knowledge of specific heat value is subject to serious and uncertain error.

In the form in which the data for values of PV occur, the volumes are given on a relative basis, making it necessary to deduce the values of PV at standard atmospheric pressure and at 32 deg. Fahr. in order to determine the mass of the gas dealt with and make it possible to express values on the basis of unit weight. In carrying this out, a difficulty was encountered because the values given are for high pressures only. This made it necessary to extend the curves in Fig. 1 outside the limits of observation values which could be done with fair safety to a point where values for the pressure of 150 lb. are measured. Curves for constant pressure are given in the paper establishing a set of values at 32 deg. Fahr.

The isothermal curves in Fig. 2 were next laid off. A and B are at the original temperatures of observation. C is established by the extension of curves in previous diagrams. Comparison of curve A with an equilateral hyperbola A^1 drawn from the point of highest pressure on the curve shows that there is a noticeable variation. The gas fails to conform to Boyle's law by a significant amount when a considerable range of pressure is involved. A calculation of the equivalent volume at atmospheric pressure for a quantity of gas flowing in a line under 300 lb. absolute pressure, if made in accordance with Boyle's law, produces an error of 4 per cent. This is an item of considerable significance when large quantities of gas are being handled. These isothermal curves give a value of n of approximately 0.99.

Equations connecting temperature and pressure at constant pressure have been found to be as follows:

DISCUSSION

EQUATION FOR CONSTANT
PRESSURE
$$\begin{array}{ll}
 P = 50 \text{ lb.,} & T = 75.4 \text{ }^\circ\text{F} \\
 P = 100 \text{ lb.,} & T = 152.5 \text{ }^\circ\text{F} \\
 P = 200 \text{ lb.,} & T = 280 \text{ }^\circ\text{F} + 50 \\
 P = 300 \text{ lb.,} & T = 427 \text{ }^\circ\text{F} + 50 \\
 P = 400 \text{ lb.,} & T = 539 \text{ }^\circ\text{F} + 80 \\
 P = 500 \text{ lb.,} & T = 584 \text{ }^\circ\text{F} + 150
 \end{array}$$
EQUATION FOR CONSTANT
VOLUME
$$\begin{array}{ll}

 V = 8, & T = 12.0 P \\
 V = 10, & T = 15.2 P
 \end{array}$$

Values of n in the equation representing an adiabatic expansion found by the temperature entropy method are given in Fig. 3. These values are seen to be about 1.17, or very markedly below the ratio of specific heats. In much of the work in which this

quantity enters it is in the form of $\frac{n-1}{n}$. When $n = 1.17$, this expression is equal to 0.145, while when $n = 1.235$, the expression equals 0.19. A value of n of 1.266, commonly employed in natural gas calculations, gives the value of 0.21 for the expression. From this it is seen that in the form in which this quantity enters into much of the engineering work, the use of specific heat ratios involves an error of 30 to 50 per cent.

The paper points out the necessity for more extended work upon the specific heat and other direct factors of methane and other hydrocarbon gases to render possible tabulations of correction factors for modifying results, obtained by Boyle's and Gay Lussac's laws, for application to commercial natural gas.

Three appendices are given, two explaining the calculations used in deriving the various curves and one considering specific heat and calculation of entropy.

CARL SMERLING called attention to an interesting point in connection with the heavier ends to the deposit in the pipe lines. He had been at work on a proposition of using those ends for the liquifying of gas, for gas production in town plants through the middle west and referred to one at Sibley, Ia., which uses liquified gas at a Bonnet gravity of 86 per cent. His company had made a special distilling process for this gasoline which was a casing head or common gas process. In distilling this product, they have been able to reduce the precipitate or residue on a cold process to approximately 8 per cent., where with the old process of using casing head gasoline at 86 Bonnet, there would have been a residue of possibly 30 per cent; the latter would necessitate the emptying of the drip tanks weekly, whereas with the new process it had not been done inside of four months. He mentioned another plant in Pleasantville, Ia., where a similar plant has been used. The Sibley plant is a pipe line system of about ten miles.

THE AUTHOR, in replying, said that the troubles from condensation referred to are not very serious so far as transmission is concerned. He stated that in the transmission of natural gas by compressors, it is not at all uncommon to have the liquid of condensation dripping out. By this it is not meant that methane gas changes to gasoline, but other gases, most of them of the paraffine group, which are present in the natural gas, will liquify under certain conditions. He stated that certain chemical changes are going on continually, having found in laboratory work that the chemical values are changing back and forth, either under heat treatment or under the varying pressure treatment.

FOREIGN REVIEW AND REVIEW OF PROCEEDINGS OF ENGINEERING SOCIETIES

ENGINEERING SURVEY

In addition to articles which can be conveniently abstracted there appear from time to time important investigations either too extensive to be used with the space available or embodying extensive tables, the reproduction of which would usually take so much space as to exclude other matter of interest. Since, however, some of these tables present matter of great interest which may be of important value to engineers in that particular line of work, an attempt will be made to present them in the form of engineering data similar to what is done in the standard engineering handbooks. In an early issue, one page will be devoted to such engineering data.

THIS MONTH'S ARTICLES

The first article describes a portable air compressor and dynamo plant, interesting because of its compactness and good design. In the same section are described governing devices used on Swiss turbo blowers, both for constant output and constant pressure, as well as a device the purpose of which is to prevent "pumping." In the previous issue of the Journal was described a Blezinger gas producer. In this issue further data on its construction are reported and tests described. The main interest of this type of producer lies in the fact that it permits the gasification of lignites high in moisture.

An article by Stribeck is abstracted showing that the law of similarity does not generally apply to phenomena occurring in notch shock tests and that it is limited by the influences due to the crystalline structure of the metal. In the steam engineering section are described devices for removing ashes and slags from a grate by suction, without permitting dust and hot gases to escape into the outside atmosphere. Further is abstracted a report of tests carried out in the experimental laboratory of the Bavarian Association for Boiler Inspection, having for their purpose to establish the relation between load on boiler and wetness of steam in the case of a Cornish boiler where it is shown that water tube boilers produce steam of greater moisture than a tubular boiler and the percentage of moisture in the latter is less than in the former. Several new types of grates are described, among them the inclined grates with compound grate bars and an improved type of hollow grate bar.

Two papers on coal dust fired reverberatory furnaces were presented before the American Institute of Mining Engineers. Before the same Society was presented a paper describing experiments on the flow of a mixture of sand and water through spigots, giving data on the relation between composition and viscosity of such mixtures. Among other things, the paper gives a definition of the term "viscosity" as applied in the case of such mixtures where not the actual viscosity of the liquid is affected but the volume rate of flow of such a mixture through an orifice.

From an advance paper of the Institution of Mechanical Engineers is abstracted a discussion on the standardization of pipe flanges and flanged fittings, containing among other

things data of an investigation as to the stresses on the flange, which the author proves to be of two kinds.

The pre-cooling of Canadian fruits and the general subject of fruit handling is discussed in a paper before the Ontario Fruit Growers' Association, where also are quoted some interesting results and a cold storage laboratory connected with a pre-cooling plant in Ontario, Canada.

The subject of forged and rolled steel pistons on locomotives is treated by W. W. Scott, Jr., in a paper before the Railway Club of Pittsburgh. The author takes up the matter from the point of view of locomotive balancing and gives some interesting data on the present tracks on the Pennsylvania lines, especially, and then proceeds to the description of a new method of manufacturing locomotive pistons, developed at the Homestead car wheel works of the Carnegie Steel Company.

Several papers are abstracted from the Journal of Mechanical Engineers, Tokio, Japan, such as the distribution of stress in a tension strap having a circular hole filled with a plug; the theory of elasticity of rods whose center line is a space curve and a paper on the transversal strength of wire guns.

From an extensive paper on the Coon Rapids hydro-electric development on the Mississippi River near Minneapolis by J. W. Links (Western Society of Engineers) data on some features of construction of interest to the mechanical engineer are reported.

FOREIGN REVIEW

Air Machinery

PORTABLE AIR COMPRESSOR AND DYNAMO PLANT

The article is devoted to the description of the Kaiser Wilhelm bridge in Fürstenwald and among other things it describes a portable dynamo and compressor installation used in the construction of that bridge. Only the latter is abstracted here.

The portable dynamo and compressor plant shown in Fig. 1 consists of a 30 h. p. benzole engine *a* with two hand feed pumps, for benzole and water. The compressor *b* of 2.2 cbm. (77.68 cu. ft.) capacity with manometer, automatic cut-off, return cooling plant, water tank *c*, air tank *d*, 16 kw., direct current dynamo *e* working at 250 volts, and transmission pump *f*. All this is located on a powerfully built truck and weighs approximately 12 tons. It carries a main frame which both carries the load and serves as a water tank. This frame carries the benzole engine, compressor and dynamo. The dynamo and compressor are driven by the engine while the cooling water pump of the compressor is driven from the compressor itself. The hot water from the compressor is led to the roof of the car, distributed there and cooled, after which it returns to the water tank and continues the same circulation. The benzole engine circulating water is cooled by evaporation.

The entire plant may be carried or loaded in a car in a single unit and can be brought direct to the work for

which it is wanted. As soon as the proper tanks are filled with water and fuel, it is ready for operation. The engine is automatically regulated by the throttling of the fuel supply. The fuel consumption is approximately 300 grams (0.66 lb.) per h. p.-hr. and cooling water lost through exaporation is approximately 26 gal. per working day of 10 hr. (*Die Kaiser-Wilhelm Brücke in Fürstenwalde a. d. Spree*, Karl Bernhard, *Zeits. des Vereines deutscher Ingenieure*, vol. 59, No. 3, p. 51, January 16, 1915, serial article, not finished, d).

TURBO-BLOWER GOVERNING DEVICES

The article describes steam turbines and turbo blowers exhibited at the Swiss National Exposition in Bern in

through. The spring *f* contracts in proportion to the pressure difference and adjusts the regulating disc so that when the amount of air delivered becomes too great, the throttling valve is partly closed, which leads to the decrease in the speed of rotation of the turbine. If on the other hand, it is desired to have a constant pressure, a similar apparatus is used, but the multiplier is eliminated so that above the piston *d*, the pressure is atmospheric.

One of the most important auxiliaries of a turbo blower governor is a device the purpose of which is to prevent "pumping." As used by Brown, Boveri and Company and shown in Fig. B, it consists of an automatic exhaust valve *c*, which at all times permits the escape of at least enough air from the pressure piping into the atmosphere or suction

FIG. 1. PORTABLE AIR COMPRESSOR AND DYNAMO PLANT

1914 by Brown, Boveri and Company. Only the part referring to regulating devices is here abstracted.

In blast furnace blowers, two kinds of regulation may be required. The more usual one, for constant output, can be brought about by means of the apparatus shown in Fig. 2 A. The governor drive is effected by means of oil pressure transmission from the turbine to a spring loaded piston *a*, actuating the main steam valve *b*. The steam admission is controlled by the centrifugal governor *c*, limiting the maximum speed of rotation, while the output is controlled by the auxiliary piston *d*. This latter is acted upon from below by the pressure in the blower pressure piping and from above by an apparatus *e* (known as the Rateau Multiplier) which produces a pressure inversely proportional to the amount of air flowing

piping so that the amount of air taken in is at all times larger than that at which the blower could start "pumping." The regulating organ proper is the piston *a*, the lower part of which is at all times exposed to the dynamic or static pressure from the pressure piping while on the upper side, there is a partial vacuum produced either by means of the "multiplier" or by simple throttling and is proportional to the amount of air delivered. Should the latter become too small, the piston goes down and through the small governor disc and permits at *e* the exit of the regulating compressed air, as a result of which the pressure of the latter below the piston *b* decreases (on account of the constant dimensions of the small exit at *f*). Thereafter, the spring *d* overcomes the opposition of the compressed air and opens the exhaust valve *c*. Since the par-

tial vacuum on the piston *a* is proportional to the amount of output, the stroke of the controlling valve, because of the presence of the spring *g*, will vary in the same sense, while the stroke of the exhaust valve will be approximately inversely proportional to the amount of air handled. In this way an arrangement can be made which would stop the efflux at a definite amount of air sharply above the "critical" limit. Fig. 1 to V in C show the various possible arrangements of the exhaust valve. (*Die Dampfturbinen und die Turbogebälse an der Schweiz. Landesaus-*

fall of the coal is determined by the properties of the fuel used and may be varied by raising or lowering the hopper pipe in the shaft. The temperature in the zone of gasification is approximately 800 deg. cent. (1472 deg. Fahr.) and this heat is used for the gasification of the coal and vaporization of the water. If the gas temperature is too high, the hopper is raised and the height of fall increases. If the gases are too cold, it shows that the height of the fall is too great and this is remedied by a corresponding lowering of the hopper pipe. At a temperature below 100 deg. cent. (212 deg. Fahr.) the water originally contained in the lignite is found in the gas stream in the form of tiny bubbles rather than of steam.

The gas is cooled in a washer to a temperature of about 20 deg. cent. (68 deg. Fahr.) which eliminates any water so that it reaches the place of combustion technically pure. At the same time, the major part of the tar is also taken out and may be used as a valuable fuel for driving Diesel engines, heating smelting furnaces, etc. By further processes of cleaning, for example by means of centrifugals, the lignite gas can be excellently adapted for use in gas engines. The gas producer itself requires practically no

FIG. 2. TURBO-BLOWER GOVERNING DEVICES

stellung Bern 1914, Professor A. Stadola, *Schweizerische Bauzeitung*, vol. 65, No. 3, p. 24, January 16, 1915, serial article, not finished, d).

Gas Producers

GASIFICATION OF ROUGH LIGNITE.

The article describes a gas producer for rough lignite and tests of the same. The producer is of the Blomlinger type previously described in *The Journal* (November 1913, p. 1692.).

Previous to charging, one of the two grate bars is heated up with a mixture of wood and lignite and carried under one of the empty gas producer shafts. The height of the

attendance during its operation as the admission of lignite is done mechanically and regulated automatically.

As shown in Table 1 most of the German lignites have been tested in these gas producers. When the gases were used in a Lancashire boiler the useful effect of over 80 per cent of the combustion zone—that is, in the front part of the fire tube was obtained with temperatures of 1200 to 1250 deg. cent. (2192 to 2282 deg. Fahr. by a Wanner pyrometer) while the temperature of the flue gases was only 190 to 220 deg. cent. average (374 to 428 deg. Fahr.). This shows that there was a fall in temperature across the boiler of about 1000 deg. cent. (1800 deg. Fahr.).

There can be absolutely no deposit of impurities in the flues and with proper regulation of air admission the combustion is absolutely free from smoke or dust. The profit from the saving of tar, which is taken at 2 per cent, is quite sufficient to cover the wages of the help at the producer. The main advantage claimed for this type of producer, however, lies in the fact that it permits the gasification of lignites containing high percentages of water (as high as 45 to 60 per cent) which hitherto could only be

used to a very limited extent. (*Vergasung von Rohbraunkohle*, R. Klostermann, *Giesserei-Zeitung*, vol. II, no. 24, p. 633, December 15, 1914, 4 pp., 3 figs. de.)

Mechanics

NOTCH SHOCK TESTS AND THE LAW OF SIMILARITY

The article reports experiments made in order to determine whether the law of similarity applies to notch shock tests.

The International Association for Testing Materials, at the Congress held in 1909 in Copenhagen, has accepted certain regulations for notch shock tests, such as the variation between the energy of blow and cross section of rupture, which the German Society for Testing Materials has called "specific energy of blow." The latter also adopted a small bar geometrically similar to the standard

the energy consumed by the standard bar. On the other hand, the International specification assumes that the energies of blow would vary as the squares of the dimensions of the bars, or that the smaller bar would require only one-ninth of the energy necessitated by the larger bar. This discrepancy could be solved only experimentally and the second part of the article describes experiments made by the author for this purpose. (Fried. Krupp Co. of Germany defrayed the cost of these experiments.)

Charpy pendulum hammers having a capacity of 110, 75 and 10 kg.—m. were used, after careful previous testing and with the resistance at no-load swinging of the hammer taken into consideration. For purposes of tests, bars were used of square section, 3 cm. and 1 cm. on each side of section, the diameter of the notch being 6 mm. and 2mm. The notches otherwise were entirely similar and reached down to the middle of the bar. The distances between

bar, but one-third the latter in all dimensions; that is, 1 cm. on the side of a square section, and the distance between supporting 40 mm. instead of 120 mm. It was expected that the proportional dimensions of both bars would permit the comparison of specific energies of blow and the Report of the Society in this connection calls attention to the experiments of Revillon which are claimed to have established the fact that when proportional bars were used, the specific energies of blow are equal.

The author for several years has held that the Revillon experiments were not conclusive and that considerations derived from the law of similarity would indicate that such an assumption ought not to be made without full tests. According to the law of similarity, one would expect that energies of blow would be related to each other as the cubes of the respective dimensions of bars and that therefore a bar one-third as large would require only 1/27 part of

supports were respectively 120 and 40 mm. Most of the bars used for the 1 cm test were made from the 3 cm bars of carbon steel, nickel, and chrome-nickel steel.

In all cases, it was found that to break the smaller bar a larger amount of energy was necessary than accorded with the law of proportionality. It was found also that the assumption of the International Association for Testing Materials made as a basis for test specification, viz. that the 3 cm and 1 cm proportional bars have the same values for the specific energy of blow is not even approximately correct, which might have been expected. What was less to be expected is that the energies of blow do not vary as the cubes of the dimensions of the bars and that the law of proportionality therefore is not applicable to notch shock tests. After it has been established that within the limits used in the experiments, the velocity of blow has no influence on the results and that there were no errors

of observation which might account for this fact, one can only ascribe it to the fact that the assumption concerning the law of similarity has not been satisfied in the test bars. This assumption is the *similarity of structures*: apparently, instead of having in the two cases proportional structures, there were similar structures. This is explained in the following manner: both the larger and smaller test bars, made of such crystalline materials as steel, consisted of grains of approximately equal size.

If, however, the rupture occurs along the lines of the crystalline formation, one can easily see that in regard to the rupture in bars otherwise proportional to each other, there exists not a proportionality but an equality. This is because when the rupture occurs along the faces of crystallization, it occurs really along the surfaces of the least resistance, and one may just as well assume that the crystalline grains are divided from one another by comparatively thin layers of material of little resistance. This will be clearer if we assume that these thin layers are located

FIG. 3. DEVICES FOR REMOVING BY SUCTION ASHES AND SLAGS

parallel to the plane determined by the notch and direction of blow. In that case, the proportional bars would consist of thinner and thicker layers of very low mechanical resistance and, although the dimensions of the bars may be different, the thickness of the respective layers would be the same. Let it be assumed further that the central plane of the notch falls in the middle of the thin divided layer and that the notch of the larger bar does not reach the limits on both sides of the thin layer of divided material. If the permanent deformation which occurs at the blow, extends only to the layers of low resistance located in the plane of the notch, the volume of which is proportional to the square of the dimensions of the bars, one cannot expect that the energy of blow will be proportional to the *cube* of the respective dimensions.

The most characteristic element of the example, the fact that the thickness of the layer undergoing deformation is independent of the ratio of dimensions, is especially evident in the case of brittle materials. In the case of tough materials, the variation between the thickness of the volume subject to change of shape is approximately proportional to the dimensions of the bars. Accordingly, the ratio of specific energies of blow in the case of bars of proportional dimensions is variable, and is unity for fragile materials.

For tough materials, it varies approximately as the dimensions of the bars. It appears, therefore, that no general rule can be established and that at any rate, the law of similarity is not generally applicable to this case. (*Die Kerschlagprobe und das Ähnlichkeitsgesetz*, R. Striebeck, *Zeits. des Vereines deutscher Ingenieure*, vol. 59, No. 3, p. 57, January 16, 1915, 4 pp., et.).

Steam Engineering

DUST-FREE SUCTION OF ASHES AND SLAGS

The article describes devices for removing by suction ashes, slags, etc. from a grate without permitting dust and hot gases to escape into the outside atmosphere.

Wherever the ash removal by suction is effected by the use of a completely closed chamber, the admission of fresh air from the outside is effected by a separate admission nozzle. There are, however, a good many cases in which an absolute exclusion of air all along the path of the ashes is for various reasons, impossible, and in this case one has to reckon with the serious disadvantage of having dust and hot gases escape on all sides. The device described in this article is claimed to eliminate this disadvantage by taking in the air for the working of the apparatus at the very places through which the dust and gases would otherwise escape.

Three designs of this apparatus are described and illustrated in the article. In the first one, a suction chamber *b* is assumed to be entirely open on top, which corresponds to a condition in which no airtight closing of the top is possible. The suction chamber *b* is shaped downward somewhat like a sack, the upper part *b* being separated from the lower part *b*¹ by a grate *n*. It is of advantage to place this grate in an inclined position and to arrange it in such a manner that it would force all the ash and slag to move toward the suction nozzle in order that the latter may have a chance to break up too large pieces of slag. This is the reason why the door *b*₂ is provided, giving admission both to the grate and to the tip of the suction nozzle *d*₁. When *b*₂ is closed, all the air required to force the material through the delivery pipe *d* is taken from above and it is impossible therefore that dust or gases should escape that way.

When larger amounts of slag or ashes drop in suddenly however, or other disturbances take place, it may happen that material would heap up on the grate, and care must be taken therefore to admit sufficient air to the suction nozzle tip *d*₁ to handle this excess of material. For this purpose, under the grate, a special passage *e* is provided which is always open on top and which admits the air taken from above through the nozzle tip *d*₁ to the suction pipe *d*, as shown by arrows in the drawing. In this case also, the fact that the air is taken in from above prevents the dust from escaping that way. But even when (in order to eliminate such disturbances as may occur) *b*₂ is left open, the admission of air for operating the suction device still remains sufficiently large to prevent the exit of dust at that place while the air is being sucked in through it.

In the second design shown in Fig. B, the suction chamber *b* is rigidly connected with the ash exit *a*. The material falls on the inclined grate *n* where exceptionally large pieces are broken up in this case also by the door *b*₂. The air admission to the suction nozzle *d*₁ occurs through an

opening in b_2 which remains entirely open, and the air is permitted to flow both through the grate and underneath it in a manner indicated by the arrows, so that in this case, even with an open damper b_2 , the dust cannot escape.

Finally, in the third design, Fig. C, the chamber b is again assumed to be open on top. Ash and slag fall on the grate u and the suction air is again taken from above, but in this case the air is admitted to the suction nozzle d_1 through the damper b_2 and in addition to that an intermediary pipe e_1 is provided, connecting the upper part of the suction chamber b with the nozzle pipe d , thus admitting fresh air to the latter as required. RELATION BETWEEN QUALITY OF STEAM AND LOAD ON THE BOILER IN THE CASE OF A CORNISH BOILER

The article reports test data on investigation showing the relation between wetness of steam and load on the boiler, in the case of Cornish boilers.

The tests were carried out in the experimental laboratory of the Bavarian Association for Boiler Inspection. The

given in Table 2. Fig. B shows the functional relations between the amount of steam produced per sq. m. of boiler heating surface and the total amount of moisture in front of the throttling valve. In order to be able to compare data previously obtained on water tube boilers with those of the Cornish boiler, the curve for the total moisture of the water tube boiler was also plotted. The figure shows that in the case of the Cornish boiler as well as in that of the water tube boiler, the moisture in the steam decreases with the increase of load, but the comparison of the two curves shows that the water tube boiler produces steam of greater moisture than the Cornish boiler and the percentage of moisture in the latter boilers is less than in the former.

GERMAN PROGRESS IN STEAM BOILER FIRING

Description of various new inventions in the field of steam boiler firing, patented in the last quarter.

H. Brams patented in Germany (No. 278513) a grate with automatic stoking and cleaning, provided with longitudinally located grate bars. As shown in Fig. 4 A, it consists of an internal rotatable pipe and other pipes ex-

FIG. 4. RECENT TYPES OF BOILER FURNACE GRATES

boiler has a longitudinal corrugated flue (Fig. 5 A), located off the center line. The boiler was put up in 1903 by the Augsburg-Nuremberg Machine factory for 13 atmospheres gage pressure. Its main dimensions are indicated in millimeters on the figure. After the hot gases leave the flue, they pass forward along the right side of the boiler, then back along the left side of the boiler, and finally escape through the smoke stack, 40 m (131 ft.) high and 0.7 m (27.5 in.) diameter of top opening. During the test, the superheater which belonged to the boiler, was separated from the fire tubes by a wall. The feed water was supplied by a duplex steam pump through a simple pipe introduced in the middle of the last section of the shell and the steam was taken out through a dome. In addition to the steam taken for the quality test, a certain amount of it was also delivered to the pump. The steam to be tested left the dome through a quarter bend directed upwards, traveled through an angular valve, then into a throttling calorimeter in the same manner as was used previously by the same laboratory for the water tube tests, and was finally exhausted into the atmosphere through a long pipe crossing the boiler room and the engine room.

On the Cornish boiler, eight tests were made with the throttling calorimeter the results of which are in the main

ternally and helically wound around it. The movement of this pipe can occur in such a manner that the internal pipe may either rotate or remain stationary while the external spiral pipes rotate either in the same or in opposite direction. This arrangement, in which the inner pipe rotates one way and the outer pipes rotate in the opposite direction, is claimed to be most appropriate for all kinds of fuels and is also very simple. One or more of the helically wound pipes b around the straight line pipe a of the grate bar help to move the fuel forward to the fire bridge. The cooling liquid flows through the water chamber q located crosswise across the entire width of the grate, the ends of the pipe a being screwed into the chamber through the stuffing boxes h . At r the pipes have openings located circumferentially, through which the liquid can flow into a rotatable hollow element e , placed about the pipe a . At e and g , the hollow element is rotatably fixed with proper packing about the inner tube. The ends of the helical pipes b , distributed symmetrically around the circumference, open (water-tight) into this hollow element e .

The drive of the grate is through worms o and p and is regulated in accordance with the speed of the fuel delivery on the grate. The internal pipe carries wheels k which are in engagement with the worm p while the hollow element e

is provided with a toothed wheel *l* in engagement with the worm *o*. The whole drive is located near the gear box *l* and the regulation of the hopper delivery is effected through the hopper door *n*. At the fire bridge end of the grate, the pipes *a* open into a rotatable hollow body *d* into which also open the external pipes, through water-tight joints. All the hollow bodies are connected through stuffing boxes *s* with the collector pipe *t* from which the cooling water is taken by the pipes *w*. At that point the temperature of water is read by a thermometer *x*. A regulating valve permits the control of velocity of flow of cooling water through the grate in such a manner that there is no scale deposit in the grate elements. In order that clinkers may not get into the packing and stuffing boxes, rotating elements *u* are provided and placed rotatably to the plane of the fire bridge so as to deflect them in falling.

In regard to inclined grates, the invention of F. Albrecht, (German patent No. 276,548) is somewhat of a novelty.

* Comparison of No. 7 to No. 5

Each grate bar consists of a frame the two parts of which are connected by a cross-piece. In this frame, stepped plates can be inserted and held on the side away from the fire. It is important to notice that the frame itself is open from behind and this permits of shoving the stepped plates quite far into the frame. In actual practice, it was found that to afford the plates an opportunity to cool they must be made so their depth is greater than their width.

Ph. Werger, who has previously patented an inclined step grate system of firing with hollow grate bars movable longitudinally, has now introduced a further improvement (German patent No. 277,330) which consists in the fact that the cheeks of the grate can be pressed against the grate bars by an angle lever which may be operated from outside either by a spring or by a weight. Fig. C and D show one design of this new type. The movable cheeks *a* which do not take part in the longitudinal motion of the other grate bars *b*, are pressed against them by the angle lever *c*. The horizontal arm of this lever located under the grate, is operated by means of a helical spring *e*, rigidly fixed on the fire wall in such a manner that the tension of that spring and therefore the pressure of the bar *a* against the grate bars *b*, could be adjusted as desired. COAL-DUST FIRED REVERBERATORY FURNACES OF CANADIAN COPPER CO., David H. Browne.

The paper describes coal-dust fired reverberatory furnaces, taking up also to a certain extent the history of the use of coal-dust for metallurgical purposes in Northern America. In the early part of the development, about 1909, it was found that at Highland Boy and Cananea, there were two mechanical difficulties encountered, stoppage of flues with the accumulation of ash, and interruptions and irregularities in the coal-dust feed. At the same time, the practice of cement plants demonstrated that the operations of feeding and burning pulverized coal could be made quite continuous, uniform, and well regulated provided that the proper methods were used in the preparation of the coal.

In the new plant means were provided both for preventing possible accidents and for regular operation of the plant. Especial care was taken to specify that all bins, conveyors, etc., for the pulverized coal should be made as nearly dust-proof as possible by the use of rubber gaskets to eliminate the danger of dust explosions. Further, to obviate the possibility of trouble from the accumulation of coal ash, an en-

tirely new arrangement of the furnace flue was designed to provide a straight-away course for the gases. In doing this, the skimming door was taken from its traditional position at the end of the furnace and placed on the side without entailing thereby any material sacrifice. As built, the original furnaces were lined with basic brick and the hearth was an inverted arch of magnesite.

The furnaces went into operation before any proper means of drying coal dust were provided and during the winter of 1911-12 a large amount of the charge, wet and frozen as it came from the piles, was shoveled in through the doors of the furnace. All the converter slag was poured in at first through an opening in the roof and later by means of an iron chute through a door near the fire end. The introduction of so much cold air and cold material prevented any satisfactory fuel ratio which at first was 6.7 tons of total charge per ton of coal but only 2.2 tons of cold charge per ton of coal. The combustion of the fuel, however, was satisfactory from the start, no trouble being experienced either in grinding or burning the coal. The ash, while working on cold charges, choked and clogged the flue at the throat and this difficulty was not eliminated until hot calcine was used and a larger tonnage was smelted. In general, the slower the furnace is working the cooler is the ash and the more it sticks and accumulates, while the faster the furnace is driven the less does the ash hang back in the furnace, and with rapid smelting it becomes a negligible factor.

During the following years, improvements in the construction of the furnaces were made. Long and shallow pockets were provided along the side walls, and through holes in the roof green ore fines were fed to protect the sides. This led to the bricking up of the doors of the furnace and the marked improvement which resulted from the exclusion of cold air and the insulation of the walls by a non-conducting and continuously renewed blanket of fines brought about the extension of this side fettling system to take in almost the entire charge of calcines. Further, as the walls were thoroughly protected by the charge, the use of basic brick in the walls and hearth was no longer necessary and it was changed to the siliceous bottom and the customary siliceous brick walls. The fuel ratio also improved very materially.

The article describes in detail the construction of the furnace. The coal-dust is introduced through five pipes 5 in. in diameter. One of these pipes is on the center line of the furnace; the others are in horizontal line with it at a distance of 3 ft. 3 in. from center to center. The coal used in firing is a good quality of slack, a thermal value of about 13,500 B. t. u. per lb., is about $\frac{3}{4}$ in. and under in size and contains about 7 per cent moisture. It is dried in a Ruggles-Coles dryer, 70 in. in diameter and 35 ft. long, and is then ground in Raymond impact mills so that about 95 per cent passes a 100 mesh and 80 per cent passes a 200 mesh screen. Any coal delivery pipe can be closed off by a slide gate and any screw conveyor can be stopped by disconnecting the beveled gears attached thereto. In this way any desired number of the five burners can be run and at any desired rate within wide limits.

The amount of air delivered to each nozzle can be varied at will or cut off entirely. As a rule all five burners are in operation, each delivering 13.5 tons of coal-dust a day. The air is supplied by a 4 ft. Sturtevant fan running at about 1300 to 1400 r. p. m. The air supplied by this fan is insuffi-

cient for the combustion of the fuel, and openings are left in the end wall between the coal burners, which are stopped by loose bricks so that the amount of air is readily controlled. (12 pp., 2 figs. d).

COAL-DUST FIRED REVERBERATORIES AT WASHOE REDUCTION WORKS, Louis V. Bender.

Description of coal-dust-fired reverberatories and results obtained therefrom.

The reverberatories at Washoe Reduction Works described in this paper have been made after an investigation of the Canadian Copper Company plant described in the preceding abstract. The coal from the storage bin is delivered to a 30 in. x 30 in. Jeffrey single roll coal crusher where it is reduced to 1 in. maximum size. It is then taken up by a belt conveyor to the foot of an elevator, passing over a Ding magnetic pulley which removes any pieces of iron, bolts, etc., and elevated and fed by gravity into a 40 ft. x 6 ft. 8 in. Ruggles-Coles drier. From here, the coal is lifted by a screw conveyor and discharged into a steel bin placed above the pulverizer, which is in a separate building from the drier. A Raymond five-roller mill is used with an average hourly capacity of 4.5 tons. To this mill is connected a fan from which air is admitted underneath the grinding surface, the material being taken away by the air current as quickly as it is reduced by the rolls and blown into a Cyclone dust collector placed 20 ft. above the pulverizer. The finished product is discharged through a spout

TABLE 3 COMPARISON BETWEEN FURNACES USING COAL ON GRATES AND COAL DUST

Furnace	Tons Smelted per Furnace Day	Total Tons Smelted	Tons Coal	Fuel Ratio		
				Excluding Drier Coal	Including Drier Coal	
No. 7	250.96	7260.31	1870.94	3.88
No. 8	475.75	14272.52	1984.77	...	7.19	7.08

at the bottom of the dust collector and is taken up by a screw conveyor to a bin placed near and above the furnace.

The method of introducing the coal from the bin into the furnace is similar to that used at the Canadian plant. The amount of coal fed is determined by the speed of the screw which is easily regulated by a Reeves variable speed regulator. The entire grinding, conveying and bin system, from the driers to the burners is air tight so far as practicable, with the result that the entire plant is extremely clean and free from dust. The ash gives very little trouble. The article contains data on the coal used and the results obtained. As to the latter, a table showing the comparison between the working of two reverberatory furnaces, one using coal grate firing and the other the coal dust firing; is given in Table 3. (9 pp., 2 figs. d.)

EXPERIMENTS ON THE FLOW OF SAND AND WATER THROUGH SPIGOTS, R. H. Richards and Boyd Dudley.

The article describes experiments on the flow of sand and water through spigots, performed in the ore dressing laboratory of the Massachusetts Institute of Technology.

for the purpose of securing data as to the relation between composition and viscosity of mixtures of sand and water. The problem to be solved particularly, as it is often encountered, belongs to the following class:

With a given quantity of solids per unit time, of a given specific gravity, to be discharged with water under a given head, and with a given ratio of water to solid, what must be the size of the spigot opening?

One of the factors affecting the solution of the problem is the viscosity of the material to be discharged and in this case the term "viscosity" has a somewhat special meaning in that it denotes the ratio of the volume of pure water that will flow through a given orifice under a given head in a given time, to the volume of the material under consideration that will flow through the same orifice in the same time under the same conditions. While the actual viscosity of water containing sand in suspension is not increased by the presence of the sand, still the volume rate at which the mixture will flow through an orifice is less

FIG. 6 CURVES SHOWING RELATIONSHIP BETWEEN COMPOSITION AND "VISCOSITY" OF MIXTURES OF SAND AND WATER

than that at which pure water will flow by reason of the friction of the particles of sand against each other and against the sides of the orifice. In other words, the flow is retarded as it would be by increased viscosity. Generally the area of the spigot opening can be calculated from the equation.

$$a = \frac{fq}{c\sqrt{2gh}}$$

in which a is the area of the spigot opening; f the viscosity of the mixture; q the rate of discharge by volume; c the coefficient of discharge; g , acceleration due to gravity and h the head of water above the spigot.

The apparatus used in the test and shown diagrammatically in the article, consisted of a cylindrical tank of galvanized iron, having a conical bottom to which the spigot was attached and a mechanical feeder for delivering dry sand to the tank. By feeding enough water into it to supply the spigot in order to maintain a slight overflow, a constant head of water was maintained above the spigot. Below the tank a swinging sheet iron launder furnished the means of deflecting the spigot discharge into a bucket

for any desired time and this determined the rate of flow. The method used in conducting the test was as follows:

The tank was filled with water and the rate of influx conveniently adjusted. The feeder was then started and sand was delivered to the tank. The sand settled through the water and passed out of the spigot, thus increasing the amount of overflow not only on account of the added volume of sand but also because of the increased rate of discharge due to the passage of the sand through the spigot. When the sand and water mixture had been running from the spigot for a minute or two and the flow had become steady, the spigot discharge was deflected into the bucket for a measured length of time, usually for about 2 min. The feeder was then stopped, adjusted to deliver sand at a different rate and another test was made. The results of the experiment are shown in a table where the rates of flow are expressed in kilograms and liters per minute, while the relationship between the composition and viscosity of the mixtures is shown graphically in Fig. 6, where the ordinates of the upper curve are the percentages of the sand by weight, while those of the lower curve are the percentages of sand by volume with the viscosity of the mixture plotted as abscissa in each case.

These tests have shown that when the amount of sand in the mixture exceeded 30 per cent by weight, the spigot would produce a very thick discharge for a short time but its continuous operation was not certain and clogging resulted sooner or later, so that the mixture of sand and water could not be successfully discharged from a spigot when the mixture contained more than about 30 per cent. of sand by weight (which for the sand used in these experiments corresponds to about 13 per cent of sand by volume). The following example, illustrating the use of the data given above, shows the practical value of this information. It was desired to discharge from the pocket of a classifier 40 tons of sand per 24 hr. together with water in the ratio of 1 part of sand to 3 parts of water by weight. The head of water above the spigot is 3 ft. and the form of the spigot is that of a short tube with a conical mouth at the influx end. The mean specific gravity of the sand is 2.81. What must be the diameter of the spigot opening?

The author goes through a complete calculation using the lower curve of the Fig. 6 for the determination of viscosity of the mixture, i. e. f in the equation on page 188, and thus determines the diameter of the spigot opening.

INSTITUTION OF MECHANICAL ENGINEERS

Advance paper D, read January 22, 1915

STANDARDIZATION OF PIPE FLANGES AND FLANGED FITTINGS, John Dewrance.

On April 18, 1902, Mr. Robert E Atkinson read before the Institution of Mechanical Engineers, a paper on the standardization of pipe flanges and of flanged fittings. As a result of it and the discussion to which it gave rise, the matter was, in the following year, taken up by the Engineering Standards Committee which appointed a Sectional Committee on Pipe Flanges to deal with the question. This committee included representatives of the Admiralty, various engineering associations and societies, and important manufacturing firms. After having held about thirty meetings, they presented a report (British Standard Tables of Pipe

Flanges No. 10, November 1904) in which the flanges are standardized into four classes according to the pressure. The report also gives standard dimensions for the short bends and tees of cast metal and for long bends of wrought iron and steel. Some of the points concerning these standards are of interest.

The diameters of flanges and bolt hole circles are uniform for flanges intended for steam pressures ranging from 55 lb. to 325 lb. per sq. in., slightly smaller flanges being given for pressures up to 55 lb. per sq. in.

One of the points which caused a great deal of discussion was whether or not the number of bolts employed should be a multiple of 4 in all cases. Hydraulic press cylinders and heads are often connected by two bolts and seldom by more than four. Cast iron pipes up to 7 in. bore for

FIG. 7 STRESSES IN PIPE FLANGES

hydraulic power up to 1200 lb. pressure per sq. in. are made with two bolts, but the reason why in English practice, only two bolts are used in the ends of hydraulic mains is that several pipes are laid side by side in the streets in branches and in order to be able to run the pipes in any direction standard tee bends and valves must be made in three variations,—one with the flanges vertical, another with the flanges horizontal and still a third with one flange vertical and the other horizontal. This led the sub-committee to the conclusion that there can practically be no standard at all unless the number of bolts used are multiples of 4. While four bolts would be sufficient for even the largest steam pipe flanges, the use of four bolts only in the larger

sizes would involve setting the bolt bracket on the flange back which is done in the hydraulic pipe flanges. This would require longer bolts which again would have to be much larger to stand the strain and would entail a greater cost than the use of the number of smaller bolts that was adopted. The clearance of 1/16 in. in the bolt holes for 1/2 in. and 5/8 in. bolts and of 1/8 in. for larger sizes was in the opinion of the sub-committee the smallest allowance that was practicable for commercial manufacture.

They did not agree to any formula as to the thickness of flanges that could be accepted for general use. The author's view is that two separate stresses have to be considered. The first is the stress necessary to distort the flange and the pipe considered as a cantilever; and the second is the stress necessary to cup the flange itself. To demonstrate this, a short piece of 2 1/2 in. bronze pipe with two of the standard flanges, 7 1/4 in. in diameter and 1/16 in. thick, was made and drilled with eight holes to the British Standard (Fig. 7 A). One of the flanges was bolted up to a cast iron flange and the other flange was connected by bolts to another thick cast iron flange, leaving space between the bronze and cast iron flanges as shown in the figure. The cast iron flanges were then pulled apart in testing machines. At 17.28 tons, the last mentioned bronze flange set 1/32 in. and at 19.2 tons had a set of over 1/8 in.

Two radial saw cuts were then made in the flange, so as to bisect the distances between one of the bolt holes and the holes on either side of it, from the outside circumference of the flange to the barrel of the pipe. In this way, a one-eighth part of the flange was isolated from the rest. A bolt was passed through the hole in this isolated portion and another through the hole in the complete flange and the cantilever strength of the smaller was tested between the centers of a testing machine in the ordinary way as shown in Fig. B. A set of 1/8 in. was obtained with a load of 1.27 tons. This experiment proved that the flange owes 1.27 tons for each section of an eight, or 10.16 tons in all, to the cantilever strength and the balance of 19.2 or 9.04 tons to the strength of the flange itself.

A flange 6 1/2 in. in diameter for 2 in. pipe and having four bolts was then taken and pulled in a similar manner. At 14.3 tons, there was a permanent set of 1/32 in. and at 16.99 tons a permanent set of 1/8 in. set. An exactly similar flange was then reduced to the shape shown in Fig. C. At 13 tons there was a permanent set of 1/64 in. and at 15.27 tons, a permanent set of 1/8 in.

This result is of great interest as it shows that formulae based on the strength of the girder between the bolts are not correct and also shows that there is an ample margin of strength when four bolts are used on a 2 in. flange. It also suggests that when it is necessary to keep the weight down as low as possible, the flange need not be round but may be a shape similar to that shown with four bolts in Fig. C, or a corresponding shape with eight bolts.

The thickness of the flanges embodied in the Standard Tables were arrived at by the sub-committee as the result of actual experiments by them. The British Standard Tables state the thicknesses for steel or wrought iron flanges welded on, the same as for cast iron flanges, notwithstanding the much greater strength of flange material in the former case.

The sub-committee did not make any recommendations

as to packings. The author states that the British Standard for pipe flanges is certainly the most largely adopted at the present time and recommends its adoption by those parts of the United States which have not already done so. (8 pp., 5 figs. g).

ONTARIO FRUIT GROWERS' ASSOCIATION

(Published in *Cold*, vol. 6, no. 4, February 1915, *Calcium*, N. Y.), Edwin Smith.

PRE-COOLING OF CANADIAN FRUITS

Discussion of pre-cooling of fruit in Canada with some historical data concerning the products of pre-cooling. Description of the pre-cooling plant at Grimsby, Ontario.

In designing the Grimsby plant, the type selected was of the warehouse design. Ice is used as a refrigerating medium in a Cooper Gravity Brine system. The fruit is loaded and packed as soon as picked from the trees on specially designed trucks which are then run into one of the four pre-cooling rooms. Each room holds more than a carload of boxes or baskets loaded on trucks and has a perforated floor and ceiling through which a circulation of cold air is blown from the coil room by means of large 60 in. fans. Electric thermometers are placed in the bottom and top tiers of fruit packages and as soon as the fruit is entered, the doors are closed, the fan set in motion and the cooling started. By means of the electric thermometers, the temperature of the fruit is taken from the outside and as soon as sufficiently cooled for shipment (38 to 40 deg.), loading takes place. Fruit once cooled down must not be exposed to the warm air until it reaches the market and therefore a cold corridor extends from the pre-cooling rooms with an adjustable vestibule to the refrigerator car door. Through this, the trucks of cooled fruit are run directly into the cold car, thus preventing exposure, rough and unnecessary handling of packages and greatly cutting down the work and time necessary for loading.

The season of 1914 has been an active one at the Grimsby plant, although there was no peach crop to handle. Cherries, pre-cooled and shipped to Winnipeg, arrived there in splendid condition and were sold on commission at 60 cents per basket, while at the same time other sour cherries were sold in the Winnipeg markets for from 38 to 42 cents, which speaks for the superior quality of the pre-cooled fruit. The plant acted also as a cold storage and effected great savings to the growers. In one case during the raspberry season when the canning factories were unable to receive berries that had to be handled at once, as much as four and a half cars of fruit were brought to the plant, placed in a low temperature for two or three days until the factories were again in shape, thus avoiding a certain loss of over \$3000.

An interesting experiment was tried in the handling of Red Astrachan apples. These apples usually go at a fairly low price but between their season and that of the Duchess, there is a scarcity of early apples. A shipper placed his apples in cold storage prior to August 15 and then marketed them as they were demanded by the trade during the latter part of the month with a gain on the transaction.

In addition to the commercial use of the plant, an experimental scientific cold storage laboratory is connected with it and its work is of great value to the grower. As an example of what it is doing, the author cites the work done with tomatoes. Tests were made on Nardiana, Chalk's Jewel and Danish Export picked at three different stages of ripe-

ness and stored in eight different kinds of packages at 32, 39 and 45 deg. It was found for example that the first two kinds are of little use for cold storage and that most of the Ontario varieties of tomatoes are too likely to crack about the stem end. A small size of tomato stores better than a large one. For storage, the tomato needs to be picked when turned to a straw color; if picked riper, it will soon become soft in storage. Tomatoes wrapped separately in the 4-basket plum crate of British Columbia kept better than those stored in open baskets. Placing the tomatoes in wood-wool proved better than wrapping, while storing in a box with a sawdust filler kept the tomatoes in the best shape, especially where they were cracked. As an illustration of the value of this class of work, the writer cites the case of a grower who came to the plant and wanted to store a carload of tomatoes until Christmas time and get the special price paid for hothouse tomatoes. He was advised against it and he would have lost the entire car had he stored the varieties of tomatoes grown.

As a matter of fact, to pre-cool fruit does not necessitate an elaborate and expensive plant. Anything that lowers the temperature of the fruit previous to shipment tends to check its ripening process and postpones decay. In British Columbia experiments have been carried on by the Provincial Department of Agriculture to show the beneficial results of using the cold night air that they have in that region and also of picking raspberries in the early morning while the dew is yet present and then removing the moisture by fanning in a dehydrator before shipping. Such an appliance cost only about \$25 or \$50, and its success made the growers quite enthusiastic. The practice of wet picking, however, is not to be encouraged where plenty of dry weather is to be had.

In pre-cooling fruit for express shipments, extreme care must be exercised not to overdo the work. In a series of investigations on strawberries, cooling has been found beneficial when carried on to the average of about 5 deg. below the temperature of the express cars. When cooled lower than this, the berries suffer on account of the condensation of moisture on removal from the cooling chamber, with a resultant growth of mold which was as bad or worse than when shipped hot from the patch. It must also be understood clearly that pre-cooling is not a panacea and will not make overripe or injured fruit arrive in good condition. At the Grimshy cold storage plant, it is the practice to refuse to receive fruit which is not in good condition, and the loading of cars is also properly controlled. On all long distance shipments, the fruit is raised 4 in. from the refrigerator car floor on a slotted rack and loaded so as to leave continuous air spaces. In the center of the car a space of from 2 to 5 ft. is left for air circulation and the loads in either end of the car are held rigidly in place by bulkheads and proper braces, which is considered about the most effective way of preventing trouble from broken packages. RAILWAY CLUB OF PITTSBURGH

Vol. 11, No. 1, November 27, 1911, Pittsburgh, Pa.

FORGED AND ROLLED STEEL PISTONS, W. W. Scott, Jr.

The paper discusses the use of forged and rolled steel pistons in modern locomotives, mainly as a means of reducing the weight of reciprocating parts and thus decreasing the dynamic disturbances at the rails.

As late as 1896, a committee of the Master Mechanics' Association, in a report on Reduction of Weight of Recipro-

cating Parts in Locomotives, called attention to the mutual relation between first cost and weight of reciprocating parts, with the main emphasis on the former. Now, however, with a tremendous increase in tonnage, weight of locomotives, wheel loads, etc., the question of weight has become as important as, if not more than, the first cost. The electric locomotive is now almost perfect so far as balance is concerned, as there are practically no reciprocating parts to be balanced. That is why the record of over 130 miles per hour made by an electric locomotive in 1903 has not yet been equalled by any reciprocating steam engine in either this country or abroad. The fastest time for a steam locomotive of which there is authentic evidence, made on the S. F. & W. on March 1, 1901, is 107.9 miles per hour and that for a very short run.

The speed of a steam locomotive is limited by the steam capacity of the boiler, and also by the liability of the locomotive to "jump the track" at excessive speed, for the reason that the vertical pressure on the rail due to centrifugal force of the over-balance in the driver increases as the square of the velocity regardless of what proportion of reciprocating parts weight is counter-balanced. Thus in every case there is a natural effort on the part of the wheels carrying the over-balance to rise from the rails at high speed. In addition to that, the author affirms that the over-balance in the drivers hammers the rails when the locomotive is in motion, and that rails do not crystallize but are broken by the centrifugal force of the over-balance coming at the time when the track is frozen rigid and cannot cushion the shock.

The speaker claimed for the rolled steel piston the following two advantages,—first, reducing the weight of the reciprocating parts and second, reducing the cylinder wear; in fact, he questions whether it would not be wise to rule that no locomotive (passenger at 70 miles per hour and freight at 45 miles per hour) shall show an impact on the rail due to over-balance more than 30 per cent within the static weight on the drivers. A similar rule is strictly adhered to by the Pennsylvania Lines East of Pittsburgh where no engine is allowed to show more than 30 per cent dynamic augment at above speeds. German railways allow only 15 per cent dynamic augment at high speed while the average for this country is 62½ per cent.

The author gives the Pennsylvania Railroad formula for calculating counter-balance required at the tread of a driving wheel based on the dynamic augment of 30 per cent, as well as the constants worked out by the Baldwin Locomotive Works for calculating dynamic augment for locomotives already in service. The author shows the advantage of light reciprocating parts on the axles of locomotives recently developed by the Pennsylvania Railroad and the Baldwin Locomotive Works and proceeds to the description of a new method of manufacturing pistons developed by the Carnegie Steel Company at its Homestead Car Wheel plant. The mogots are cast according to the usual open hearth furnace practice in moulds 22 in. by 22 in., about 6 to 7 ft. long. After stripping and soaking in the furnaces, they are rolled into round blooms, 15 in. in diameter and while hot, sheared into "cheeses" of the proper weight to produce the required section. The important element is the further forging and rolling work and it is very important to bear in mind that the blocks are now sheared from rolled rounds into the form of discs rather than from flat slabs into the form of squares,

as was done some time ago. This difference in procedure is the keystone of the present day success of rail steel sections and various types of wheels and is due to the fact that the outside of the ingot which according to the nature of the elements composing it, is its best part, finally becomes by this process the outside or periphery of the section while the center, naturally the weakest part, finally becomes the core and goes back into scrap.

After inspection, the discs are taken to the wheel plant. There by means of a steel dog running between two rails, the disc is transferred to a hydraulic press, the function of which is to pierce a hole considerably smaller than the rough bore desired, about half way up from the center on the axis of the disc, in order that the disc can be held between the rolls on a pin until the hydraulic pressure applied grips the piece and forging commences.

The author describes in detail the mills used and the exceptionally heavy equipment necessary to work high carbon steel into annular sections. After rolling, the piece is put through a shear which automatically trims it of the flash usually present in flat forging. In the same machine the core is punched out, thus freeing the steel of any undesirable segregation that may happen to be present after the discard from the round bloom has been made at the blooming mill shears.

An experiment was made to trace the movements of the center of the ingot during the process of manufacturing an annular section. A bar of copper 1 in. in diameter was inserted in the hole drilled through the axis of the disc while cold. The disc was then heated and worked in the usual manner. After the core had been punched out, it was split longitudinally with the copper bar. The latter was found to have varied from its original position slightly less than an inch, the maximum variation from the center line occurred about half way through the section, indicating that the steel had been thoroughly worked all the way through.

Among other things, the author takes up the question of the working of the piston against the cylinder. He states that a close investigation will show that a fair percentage of cylinders wear on the top side due in part to inferior line guides, loose crossheads and to the fact that when the locomotive is working under steam, the pressure works first under the piston rings and tends to throw the piston forward against the top of the cylinder. In order to prevent the piston from scoring the cylinder's face, the author suggests following the practice of designers of heavy stationary engines when using solid rolled steel pistons in locomotives; to cut one or more dovetail grooves in the face of the piston, insert segments of good malleable bearing metal and hammer it solidly into the dovetail grooves. This has an added advantage of forming an oil groove or pocket between the piston rings and bearing metal face. Another suggestion is two rings of bearing metal. The solid rolled steel pistons for the Pennsylvania Railroad are used with extended hollow piston rods which have the advantage of reducing the cylinder wear and simplifying lubrication.

The author states that he has made laboratory tests of a new plate ring metal which showed an "exuding" point of 1150 deg. Fahr., which can be easily pinned into a dovetail groove $\frac{1}{4}$ to $\frac{3}{8}$ in. deep and which has an average scleroscopic hardness of 8.

THE DISTRIBUTION OF STRESS IN A TENSION STRAP HAVING A CIRCULAR HOLE FILLED WITH A PLUG, K. Suehiro.

The paper is an extension of a previous paper entitled *The Distribution of Stress in Plates having Discontinuities and Some Problems Connected with it.* (Published in *Engineer* in 1911).

In the present paper, the author treats mathematically the case of plane stress where the plate is not only strained in its plane but also in the direction of the normal to the plane. It is assumed that a rectangular thin elastic plate is pierced with a circular hole in its center and filled with the plug and that it is then subjected to edge traction in its plane, normal to the sides, the breadth of the plate being supposed to be sufficiently large as compared with the size of the hole so that the displacement of a distant point is not influenced by the presence of the hole. It is next assumed that the plug is of the same material as the plate and just fills the hole without exerting any initial stress on the plate. The author treats the problem by a strictly mathematical method and comes to the conclusion that an engineering structure can be partially relieved from stress concentration due to the presence of the hole by filling the hole with the plug (11 pp., 3 figs.).

THEORY OF ELASTICITY OF RODS WHOSE CENTER LINE IS A SPACE CURVE, T. Matsumura.

The paper develops a general theory of elasticity of rods whose central line is inside curve, this theory being then applied to the problem of spiral springs.

In the course of his investigation the author develops the main questions governing the deformations of such rods and shows how they can be applied to the determination of the deformation of cylindrical spiral springs; first, when a spring is held at one end and subjected to tension by an axial load applied at the other end and second, when the cylindrical spring used in a shaft governor, revolves around the shaft in the plane perpendicular to it. In each case when the angular velocity is high, the elongation is considerably affected by the centrifugal force of the spring itself.

TRANSVERSAL STRENGTH OF WIRE GUNS, M. Okochi.

The article discusses the question of transversal strength of wire guns, a problem which has hitherto been treated

with respect to one particular type and which the author attempts to treat in a more general manner. He establishes the fundamental equation for the distribution of stress in a thick, walled hollow cylinder of which the surfaces are exposed to certain external and internal radial pressures, assuming that the distribution of temperature inside the walls of the ordnance piece (although there are no precise data to support such an assumption) occurs in accordance with the Fourier theory of the conductivity in homogeneous materials and that because of the shortness of duration of the external pressure, it is stationary. He passes then to the consideration of an equation for distribution of stresses in a supposititious wire gun having no solid core and made exclusively of thin wire, and from this, to the consideration of a wire gun with an inside core for which he derives an equation showing the distribution of stress in three directions, both in the core and in the wire elements and also gives expressions for the total stresses in the wire gun at the instant of discharge. Among other things, he shows by his formula for the stress in the wire both in the stationary state and at the instant of discharge, that different states of stress can be obtained with the winding tension maintained constant and derives an expression for the winding tension giving equal tangential tensions.

He proceeds then to the consideration of the strength of large caliber wire guns of complicated structure and fully establishes the mathematical equations for stresses in such cases. Further, in order to facilitate the calculation of the strength of wire guns by his formula, the author gives a table showing the values of the co-efficients used therein. The matter is handled in a strictly mathematical manner and therefore is not suitable for abstracting.

WESTERN SOCIETY OF ENGINEERS

Journal, vol. 19, no. 10, December 1911, Chicago.

Some Aspects of the Work of the Illinois Utility Commission. Robert M. Feustel.

Coon Rapids Low Head Hydro-Electric Development on the Mississippi River near Minneapolis. J. W. Link (abstracted).

COON RAPIDS LOW HEAD HYDRO-ELECTRIC DEVELOPMENT ON THE MISSISSIPPI RIVER NEAR MINNEAPOLIS, J. W. Link.

Description of the low head hydraulic development with a total fall of about 165 ft. or an average fall per mile of 2.75 ft.

One of the most interesting features of this construction is the way the foundation is set up. Owing to the wide variety of ground encountered, a hollow structure is carried on piles so as to insure against unequal settling as much as possible. The possibility of a blowout against the structure was provided for by enclosing the whole area of the dam and powerhouse with steel sheet piling, driven to such a depth as to penetrate well into what was assumed to be impervious material, that is, impervious under the pressures which are present in this particular case. A working load of only 10 tons per pile was allowed under all of the structures except the powerhouse, such a load limit being used in order to have a closer spacing of the piles and thus insure a more uniform distribution of the loads. In driving the piles careful watch was kept of the penetration and the bearing value of the pile was figured by the Engineering News formula. At the south end of the spillway where compact clay rises to the bed of the stream, it was

found impossible to drive either sheet steel piling or round piles and instead of that, concrete walls were substituted, the concrete being placed in the trenches without forms. A method of carrying on the excavation was used which involved driving the pile after the excavation was completed. This resulted in the heaving of the bottom and the distorting of the braces but the work was carried through to a successful finish by tying the bracing down to the heads of the piles already driven. This did not entirely stop the distortion and buckling of the bracing but prevented it from collapsing. Provision was made in the foundation for taking up the horizontal forces so as to prevent movement of the structure down stream. This was done partly by driving inclined piles and also by carrying out buttresses down stream between the draft tubes, each buttress resting on a cluster of 32 piles driven to refusal.

The Tainter gates used in the plant have no cross bracing. They are built up of I beams which span the opening and are attached to plate girders at the end. From the girders, struts extend to the pins which support the gates and upon which they hinge. Between the beams and the struts gusset plates are inserted instead of the usual cross bracing, the cover plates being riveted to the flanges of the I beams. Gates formed in this way will require somewhat more metal and will possibly cost slightly more than the others, but have the advantage of being less liable to damage in case they are overtopped by flood. They are made watertight on the bottoms and ends by the use of rubber belting. The hoists for these gates consist of two stands with chain drums driven by a worm gear, the worms in their turn being driven by a line shaft in one piece. The hoists are arranged for hand or electric motor operation, the latter being provided only for emergency cases where it is desired to open the gates quickly; so far, no motor has been installed.

The expected annual output from the plant as it stands (5 units) is 52,000,000 kw-hr. and 64,000,000 kw-hr. from the complete installation of 7 units. The generating units are of the vertical type consisting of Allis-Chalmers single-runner Francis turbines direct connected to General Electric alternators and fitted with roller thrust bearings and oil pressure governors. The turbine runners having a mean diameter of 8 ft. 6½ in. and a diameter over the discharge ring of 12 ft. 8 in., are set in concrete scroll cases with cast iron pit rings. The wheel gates, which control openings 54 in. high by 13 in. wide, are of the swivel type with exterior operating ring and links.

The rotating element of the machine is carried by a roller thrust bearing which rests on the upper spider of the generator, and the length of the shaft from the center of the runner to the top of the roller bearing is 21 ft. 6 in. A water lubricated lignumvitae guide bearing is carried by the upper cover plate of the turbine and an oil-lubricated guide bearing is carried by the upper spider of the generator just below the roller thrust bearing. The shaft has a flanged coupling 3 ft. 7 in. above the lower guide bearing. The lubrication of the roller bearing and the upper guide bearing is secured by a unit oiling system. The oil filter, storage tank, and circulating pump are located in the wheel pit. The motor-driven rotary circulating pump is mounted on the oil tank and forces the oil up to the bearings, the return of the oil to the filter being by gravity (37 pp., 25 figs. d).

MEETINGS

LOS ANGELES, JANUARY 15

A very successful meeting of the Los Angeles Section was held on January 15. Prof. Walter H. Adams read a paper on the "Diesel Engine and its Application to Southern California. The paper was of particular interest in view of the extensive oil development in Southern California, and it was discussed by Messrs. Clark, Clapp, Harris, Finkle, Gerhardt and Weeks.

MINNESOTA, JANUARY 28

On January 28, the Minnesota Section held a joint meeting with the Western Association of Electrical Inspectors which was holding its annual convention in Minneapolis. At this meeting, Charles L. Pillsbury, past vice-chairman of the Minnesota Section, gave an address on the Principles Entering into Valuation of Public Utilities and Rate Making. Mr. Pillsbury gave a very strong address and treated especially some of the fundamental principles involved in rate making and valuations of public utilities, citing from a large number of supreme court decisions as his authorities.

NEW YORK, FEBRUARY 9

At the monthly meeting of the Society in New York, held on February 9, an address was delivered by Edwin J. Prindle, of New York, a patent expert, on A Proposed System of Classifying and Digesting the Records of the Society to Render Immediately Available all Information on Each Branch of Every Subject. Mr. Prindle proposed an ambitious plan of indexing technical literature with special reference to not only properly classifying all the valuable information contained in the records of the Society, but also so digesting all papers and articles in the records that each phase of every subject treated shall be referred to.

This will, he thinks, obviate the necessity of patiently going through every paper page by page to ascertain whether the information desired is available. The plan is based on the experience of the United States Patent Office in classifying inventions in general and mechanical inventions in particular. Mr. Prindle explained the system of digesting law books in considerable detail, and pointed out the features so thoroughly tried there, which are applicable in a corresponding system for the Society's records. He showed illustrations of the record cards that would be used in the system proposed and indicated the various forms that the indexing would take for classifying different subjects.

The proposed plan was extensively discussed. In general, it met with favor, except that the majority of the discussors expressed regret that it should be limited to the works of the Society alone, whereas the plan could be made so much more useful by extending it to cover the transactions of the other great engineering and technical societies. The difficulties of a work of this magnitude were then pointed out, and much general discussion followed, notable among which was the suggestion in a written discussion from Henry Hess that the matter be laid before the Engineering Foundation, recently established in New York for promoting research work.

MILWAUKEE, FEBRUARY 10

At a meeting of the Milwaukee Section on February 10, L. G. Warren, resident Engineer, gave a lecture on the new Linwood Avenue Intake tunnel.

The paper describes the construction work done on the tunnel and shaft. The contract was executed by Joseph Hanreddy & Company of Chicago, Illinois.

The compressor plant was operated by motors from current taken from the local electric company. It consisted of a 2 stage Ingersoll Imperial type No. 10 compressor, capable of delivering 1,000 cu.ft. of air per minute and two single Ingersoll Imperial type compressors capable of delivering 700 cu.ft. of air per minute. The first compressor was used to furnish air to the drills and pumps in the tunnel and the second for furnishing air to the tunnel when it was under air pressure and also for furnishing air to the pumps in emergencies.

The method of excavation is described in considerable detail. The material encountered consisted chiefly of red clay, hard pan and brown shale, the latter requiring blasting for removal. In the completed shaft, the hoist form was made of 12 x 12 timbers. It is divided into two compartments each provided with guides for one cage. Two cages operated on a breast cable by means of an electric hoist, were in constant operation. These cages then conveyed both the in-going and out-going mules and also the laborers. A set of air locks were installed at station 0 plus 75. It consisted of one material lock and one man lock. The material lock is composed of 3½ in. boiler steel, being 7 ft. in diameter and 20 ft. long. The man lock is composed of 3½ in. boiler steel, being 3½ ft. in diameter and 12 ft. long. It has been necessary to use these locks for one emergency, which will be described later.

All of the concrete was mixed in a one-yard Smith Mixer situated on the surface. From the mixer, the concrete is dumped into the tunnel cars and then by the cage into the tunnel where it is hauled by mules into the forms. The forms are composed of steel plates and angles with the side walls and arch forms separate. Each of these forms rests on wheels which are supported on movable rails, so that the forms can be advanced by means of the hoisting engine on the side wall form. The side walls and the arch are placed by separate operations, the side walls being placed in advance of the arch. About 100 feet of the invert has been placed adjacent to the shore shaft, leaving the remainder to be placed after the completion of the arch and side walls. The reinforcing rods in the side walls are driven 18 in. into the shale bottom, so that they may be removed by excavating beneath the side walls, and a bond secured with the reinforcing rods in the invert when the invert is placed.

The paper describes in detail the water inflow system used as well as the method of ventilation. The latter was effected by a 6 in. fan, rated at 3675 cu.ft. per minute.

For warning measures, two miners' safety lamps are constantly maintained in the heading, one suspended on the timber above the platform for the forms for concreting the side walls and one suspended on the roof timber about 8 ft. back of the face of the heading. The City's inspectors, and the contractor's men have been instructed in the use of these lamps for the detection of methane.

BUFFALO, FEBRUARY 11

At a meeting of the Engineering Society of Buffalo on February 11, C. H. Bierbaum delivered an address on Bearings and Their Lubrication. Mr. Bierbaum has been making a special study of this question for the past seventeen years and gave a very interesting lecture which was fully illustrated by drawings on the blackboard. He explained the fundamental principles connected with the design of bearings and arrangements which should be made for their proper lubrication. His address was interspersed with accounts of actual tests which have been made and troubles which have been remedied from actual practice. In addition, he explained the various formulae, etc., which have been developed in connection with this work and the consensus of opinion from the members after the lecture was, that he had presented one of the most interesting addresses so far given and one which was of great practical value to the 120 members present.

ATLANTA, FEBRUARY 12

A meeting of the Atlanta Branch of the Society was held on February 12. The meeting took the form of a luncheon at which a general discussion took place relative to the welfare of our local branch and prospects for the future. It was decided to hold these luncheons once a month in order for the local members to keep in closer touch with each other and to advance the general interests of the branch.

BOSTON, FEBRUARY 15

The Sixth Annual Joint Engineers' dinner was held on February 15 and was the first public function to be held in the new Boston City Club Building. Among the speakers were the following: His Excellency Governor David I. Walsh, Dr. Allan McLaughlin, Mr. Charles H. Eglee, Captain Robert W. Bartlett, the Presidents of the Local Engineering Schools and the Presidents of the Engineering Societies. There were about 250 in attendance.

NECROLOGY

JOHN HENRY CLARK

John Henry Clark was born in Cornwall, England, on April 7, 1859. As a young man, he served an apprenticeship as a machinist in the shops of Cooke, Rymes and Company at Charlestown, Mass., and also with the Whittier Machine Company in Boston, Mass., and afterwards became superintendent of the works of the latter company. He was also associated with Hon. Oliver Ames, formerly governor of Massachusetts, who was interested at that time in the development of an oil engine.

In 1890, Mr. Clark took a position with the Thomson-Houston Motor Company which was one of the companies affiliated with the Thomson-Houston Electric Company for the purpose of exploiting the electric elevator business. This company afterwards became merged in the General Electric Company which was organized in 1892. When its power and mining department was formed, Mr. Clark was connected with it and continued in that department until his death. He was transferred from Boston to Schenectady in 1895.

Mr. Clark was a member of the Boston Engineers' Club and the Engineers' Club of New York. He died at Schenectady, January 3, 1915.

CHARLES WARD

Charles Ward was born in Leamington, England on March 5, 1841 and came to America in 1871. He had been trained as a gas engineer in England and almost his first work in America was in Charleston, West Virginia where he installed the first gas works. He later became superintendent and general manager of the company.

Mr. Ward came into prominence before the engineers of the country when the late Admiral McVilleville invited the makers of water tube boilers to compete for supplying the boilers of the coast defense vessel Monterey. Mr. Ward's boiler was tested in 1890 and proved so noteworthy for the length of the test under severe conditions and attained such excellent efficiency that four boilers of this type were installed on the Monterey. Mr. Ward thus has the credit of the first installation of water tube boilers on a large war vessel.

Even before this, smaller water tube boilers of a different design manufactured by Mr. Ward had been used in steam launches of the United States Navy and they have given such satisfaction that the Navy Department has continued their purchase and use to the present time.

Mr. Ward was also a pioneer in the use of screw propellers on western river steamboats in the effort to reduce waste and increase efficiency as compared with the time honored stern wheel boats, which are almost exclusively in use. Some years ago, he carried out a repetition of the famous test in England during the first half of the last century of a tug of war between a screw propelled boat and a stern wheel boat of the same power. In the later case as in the earlier one, the screw propeller showed the better results.

Mr. Ward died in Charleston, West Virginia, on January 17, 1915.

HENRY SELBY HAYWARD

Henry Selby Hayward was born at Brooklyn, Long Island, September 19, 1845. His parents moved to Elizabeth, N. J., in 1852; was educated at Rev. David H. Pierson's School in Elizabeth; entered the Novelty Iron Works at the foot of Twelfth Street, New York, in 1862, and there served a four years' apprenticeship in marine construction work and engineering.

In July 1866, he entered the service of the Pacific Mail Steamship Company and made a voyage on the steamship "Montana" through the Straits of Magellan to San Francisco. He was sent back to New York via the Isthmus of Panama and returned in July 1867, on the steamship "Great Republic," to San Francisco, via Straits of Magellan, as assistant engineer. The "Great Republic" sailed from San Francisco for Japan in September 1867, the first regular steamer on the Japan and China route of the Pacific Mail service. After several voyages between San Francisco and Hong Kong, he was detailed to service on branch lines and spent about four years' service on the steamers "Hermann," "New York," "Costa Rica" and "Arizona," plying between ports in Japan, China and Siberian coast. During that period he filled positions as second and first assistant and acting chief engineer on the different steamers.

Mr. Hayward returned home November 1872 on three months' leave after six years of continuous service, but while home he decided to resign, and entered the service of the Pennsylvania Railroad Company April 1, 1873, as machinist

in the Altoona shops. He was subsequently detailed to duty in draughting room, and in 1874 was detailed for special duty on the United Railroad of New Jersey Division, with title as assistant road foreman of engines. He was appointed assistant superintendent of motive power, United Railroad of New Jersey Division, April 1, 1875, to which the marine department was subsequently added in 1881.

On October 1, 1882, he was appointed superintendent of motive power of the United Railroad of New Jersey Division, and was also made superintendent of motive power of the West Jersey Railroad in 1883, and the Camden & Atlantic Railroad, including the ferries and floating equipment on the Delaware River, in 1884. He had supervision of the motive power and marine equipment of the New York, Philadelphia & Norfolk Railroad from January 1, 1890, until his death.

During the 80's he took out several patents, one being for an interior check valve on locomotive boilers, another for a car journal box, and still another was a cut off valve for beam engines. This cut off valve was practically adopted by all the ferries in New York Harbor.

He had been a member of the American Society of Mechanical Engineers since March 1, 1882, and of the Society of Naval Architects and Marine Engineers since May 1893. He was also a member of the Engineers' Club of New York, the Engineers' Club of Philadelphia, and the New York Railroad Club.

PERSONAL NOTES

James F. Monaghan, until recently associated with the Waltham Bleachery & Dye Works, Waltham, Mass., has opened an office in Boston, as an engineer and specialist in the engineering of processes and equipment relative to the bleaching, dyeing and finishing of cotton and linen piece goods.

James A. Gish, Jr., has become affiliated with the Nebraska Portland Cement Company, Superior, Neb., in the capacity of plant manager.

Alfred C. Nelson announces that he has opened offices in the Rockefeller Building, Cleveland, O., as consulting and contracting engineer.

William H. Smead has closed his office in the Citizens Building, Cleveland, O., and has taken charge of all mechanical work for the welfare department of the City of Cleveland, including designing new power house plant and heating plant at the new City Hospital, and mechanical improvements at the Cooley Farms.

Egbert Moxham, until recently associated with the E. I. du Pont de Nemours Powder Company, Wilmington, Del., as assistant manager of the development department, has accepted the position of general manager of the Aetna Explosives Company, New York.

George F. Murphy is now associated with the Heine Safety Boiler Company and will have charge of their sales offices at Pittsburgh, Pa. He was until recently sales representative in charge of the eastern branch office of Busch-Sulzer Bros. Diesel Engine Company of St. Louis, Mo., with headquarters in New York.

The following members of this Society have been elected to offices in the Engineers' Club of Philadelphia: J. W. Ledoux, President; D. Robert Yarnall, Vice-President; L. H. Kenney, Secretary; J. E. Gibson, Director.

STUDENT BRANCHES

ARMOUR INSTITUTE OF TECHNOLOGY

The fourth regular meeting of the Armour Institute of Technology Student Branch was held on the evening of February 4. F. L. Faulkner '15 presented a paper on the Adaptability of the 8 Cylinder V-Type Motor to the Automobile. Slides were used to show the different types. A general discussion followed the paper.

BROOKLYN POLYTECHNIC INSTITUTE

The first meeting of the Brooklyn Polytechnic Student Branch was held last October. At this meeting, Theodore B. Merkt gave a very interesting lecture on Sun Power Plants.

Another meeting of the Branch was held on November 7. J. A. Kinkad of the Parkesburg Iron Company gave a very interesting lecture on Charcoal-Iron Boiler Tubes and George Wieber talked on Diesel Engines—Their Application to Marine Work.

At the meeting on January 9, Arthur V. Farr of the S. K. F. Ball Bearing Company gave a talk on Present Day Applications of Ball Bearings.

The fifth meeting of the Polytechnic Student Branch was held on February 6. The meeting was unique in the fact that for the first time student papers composed the evening program. Three papers were presented: Ice Making by Samuel P. Blakeman; Friction Losses in Universal Joints by Murray Harris; and Present Day Locomotive Practice by Merritt Van Valkenburgh.

CASE SCHOOL OF APPLIED SCIENCE

On February 11, at a meeting of the Case School of Applied Science Student Branch, Russel C. Manning '15 gave a paper on Electrification of Steel Mills. He discussed reasons for installing the electric drive in rolling mills as against the steam drive as used formerly. It showed that though the first cost was greater, the economy of operation of large producer gas engines direct connected to the alternating current generators offset this increased first cost to such a degree that they were coming more and more into use. The method of operation of the mills when driven electrically was discussed and the fact was brought out that even in the case of reversing mills, motors were proving more effective; a few power and cost figures were given to show this. The paper was discussed by A. P. Armington, L. K. Baker and L. W. Hodons.

COLORADO AGRICULTURAL COLLEGE

A meeting of the Colorado Agricultural College Student Branch was held on January 18. Mr. Searles gave an interesting review of the article Steam Locomotives of To-Day from The Journal of January, 1915.

Professor Train then gave a short talk on the Locomotive Testing Plant at Purdue.

COLUMBIA UNIVERSITY

At a meeting of the Columbia University Student Branch on January 8, Prof. Sidney A. Reeve, formerly of Worcester Polytechnic Institute gave a lecture on Heat and Work. Professor Reeve by clever and interesting analogies gave a very clear conception of heat and entropy. He compared our oceans of water to the oceans of temperature surrounding us toward which all temperatures fall. Further comparisons with the mechanics of motion, movement of celestial bodies, molecular motion and vibration proved interesting and extended the vision on the subject.

CORNELL UNIVERSITY

The Cornell University Student Branch held a meeting on January 22, at which Elmer A. Sperry, President of Sperry Gyroscope Company, Brooklyn, N. Y., gave a lecture illustrated with lantern slides and experimental demonstrations on the theory of the gyroscope, its present applica-

tions and the widening field for its use. In naval use, it proves its worth as a compass, as a stabilizer for the ship itself or for telescopes, horizon finders or the like, for recorders of pitch, roll and angle of yaw. It has similar uses on aerial craft.

KANSAS UNIVERSITY

On January 21, at a regular weekly meeting of the Kansas University Student Branch, O. H. Ruhl gave a report of his visit of last November to the plant of the Western Electric Company at Hawthorne, Ill. His talk was general and by means of a chart he showed the layout of the entire factory and the arrangement of the buildings and pointed out the advantages of such an arrangement. Some stress was laid upon the shipping facilities and the warehousing methods of the company. He spoke also of the advantages offered by the company to its employees in the way of protection of health, physical exercise, social amusement, etc. Quite a lengthy discussion followed among the members of the Senior Class who visited the plant on their fall inspection trip.

Dale S. Mills reported on the Industrial Engineering magazine. He chose for his subject the refrigerating plant of the Sargeant Wharf Station of the Quincy Market Cold Storage and Ware-house at Boston, Mass. Most of his discussion was on the new 1000 ton compressor used at this plant, which is the largest compressor ever built, and spoke somewhat in detail of the construction of the parts for this massive machine.

At a meeting held on January 28, at the home of Dean P. F. Walker, Prof. C. C. Young of the water analysis department of the University of Kansas gave a lecture explaining the causes and effects of bad water used for feed water in boiler plants. He also showed how boiler scaling could be prevented by different means of water softening and cited instances where such prevention has been successful, and pointed out the fact that any boiler plant can save money by installing a water purification plant instead of using the old means of removing scale with tools for that purpose, except in a few very rare cases where soft water is available. Not only does the installation of such a plant save on labor, but very materially saves on the life of the boiler. A good discussion followed by Dean P. F. Walker and Prof. A. H. Sluss, Superintendent of the power plant at the University of Kansas.

LEHIGH UNIVERSITY

At a meeting of the Lehigh University Student Branch on December 10, W. F. Roberts, superintendent of the Lehigh Plant of the Bethlehem Steel Company gave a paper on Ordnance.

W. J. Bailey, special student at the University read a paper on Naval Architecture.

MASSACHUSETTS INSTITUTE OF TECHNOLOGY

The Mechanical Engineering Society held its first meeting since the mid-year vacation on February 17. This was the first lecture meeting for some time, the most of the activities of the Society this year having been confined to trips to various large factories.

Harry Gay of the Stone and Webster Engineering Corporation gave a most interesting talk on The Equipment of the new Technology. Mr. Gay confined himself more to the administration connected with the equipping the new buildings than to the pieces of apparatus and the like which are being installed. His talk showed very well the vast amount of work which must be done to avoid errors in the final product when so much is at stake. His remarks also showed very well the nature of the work in an up-to-date drafting office.

OHIO STATE UNIVERSITY

At a meeting of the Ohio State University on January 14, W. A. Converse chemical director of the Dearborn Chemical Company of Chicago addressed the members of the branch on Treatment of Boiler Feed Waters. As the engineer is usually more or less familiar with the scale forming action

of water, Mr. Converse limited his talk to the corrosive action alone, which until quite recently had received little attention. He stated that waters containing no scale forming substance were not necessarily harmless, but might be highly corrosive. He cited a case where the analysis indicated the water to be very satisfactory but that it corroded or dissolved the pipe lines through which it passed so badly that it was necessary to replace them once every six months.

The speaker discussed briefly the physical and chemical properties of water and traced its passage from the vaporous condition in the clouds through the atmosphere, the surface of the earth and the lower strata of materials, and told just what substances were absorbed, and also discussed several typical analyses of boiler feed waters and indicated how the engineer is likely to be deceived.

The causes of pitting and some of the modern theories of electrolytic action were spoken of, and lantern slides illustrating experiments which tended to prove these theories were presented.

PENNSYLVANIA STATE COLLEGE

At a meeting of the Pennsylvania State College Student Branch on January 18, the following officers were elected: W. D. Garman, president, V. D. Longo, vice-president and J. L. Sprengle, secretary.

STEVENS INSTITUTE OF TECHNOLOGY

On Wednesday, January 16, a party of eighteen students under the guidance of the Stevens Engineering Society visited the Otis Elevator Company's plant at Yonkers to inspect the various departments. The society was very fortunate in obtaining the privilege of visiting this plant through the kindness of the Vice-President of the company for according to rule, inspection of the plant is forbidden.

On February 10, the society conducted an inspection trip, to the National Biscuit Company's plant.

SYRACUSE UNIVERSITY

The first important meeting of the new semester of the University of Syracuse Student Branch was held on February 9. Plans were made for conducting a series of "Personal Efficiency" lectures to be under the direction of W. C. Dexter, chairman of the branch and which are to be given at each of the bi-weekly meetings. In addition to this, they have prepared a short series of lectures on the Working of the New Workmen's Compensation Law in New York State, on the History of the Electrical Industry in this Country and on Banking.

The Student Branch voted at that meeting to challenge the Senior Electrical Engineers to a debate in the near future. Two questions will be submitted to them for their choice: Should Military Training be Compulsory in the Colleges of this country and Should Arbitration in Labor Troubles be Compulsory?

On February 12, an illustrated lecture on Submarines was delivered to the entire student body of the Engineering Department by G. E. Furbush, Secretary of the Student Branch. The history of submarine boats was traced from the crude efforts of Symons in 1747 up and through the present time. Much detailed information regarding modern practices in this country and abroad was presented. It is hoped that it may be possible to use a more complete abstract of this paper in an early issue of The Journal.

THROOP COLLEGE OF TECHNOLOGY

At the regular meeting of the Throop College of Technology Student Branch on January 28, Paul Weeks, representative of the Baldwin Locomotive Works and a member of the Society, gave a very interesting talk on some of his experiences as an engineer. He pointed out some of the difficulties which he met with and showed how he overcame them.

UNIVERSITY OF COLORADO

In the January issue of The Journal a brief account was given of a meeting of the Student Branch at the University

of Colorado, Boulder, at which a lecture was given by Charles M. Hampson of Denver. The lecturer discussed the square deal in engineering and the ethics involved in the work of the mechanical engineer, and it is believed that the following extracts from the lecture will be of general interest to members of other sections.

Mr. Hampson said that while the engineer of the past had to know his machine shop and foundry practice, his drawing board and steam plant, to-day he must also understand ions and ohms, amperes and resistances and must be a fair all round civil engineer as well. The chances are that the men who are backing an undertaking do not know the first principles of engineering and the mechanical engineer is naturally the custodian of their money and is largely responsible for the success or failure of the undertaking. It is to his advantage to have a reasonable, practical working knowledge of the essential details of engineering in its various departments.

The speaker quoted statistics with regard to salaries of engineering graduates which indicate that the average mechanical engineer receives sufficient compensation so that he can well afford to give of his best.

Speaking of the square deal, he said: Square, according to Webster, means "forming a right angle, true, upright, honest, just." Deal means a bargain or understanding. Could we have a better watch word? A right bargain. Remember this: A square deal means a true understanding.

There are no mistakes in the engineering profession; it is the only profession that does not recognize the word. A trained engineer has no excuse for a misconception. Engineering is an exact science so far as it goes. The engineer should not attempt to go further than his knowledge. When in doubt he should stop.

We all know when we are in the right and when we are not right. We all know good work, square work, and we must insist upon that sort of work or none.

In tearing down an old house in Milwaukee some years ago surprise was expressed by the workmen at the standard size of the timbers. The 4×4 s were actually 4 in. by 4 in. and the 2×6 s really were 2 in. by 6 in. How many houses built in these later years can show such measurements of dimension stuff?

If it were now desired to use timber in construction work that was full dimension it would be necessary to place the order with the mills well in advance and pay an additional price of at least two dollars per thousand over the regular price. Think of it; you specify a certain sized piece of timber and are then compelled to use a piece from 10 to 20 per cent smaller. How about the factor of safety? The only way to get a square deal is to specify absolute sizes and make allowance in the cost sheet.

During the past fifteen years it has been my duty to handle a great many yards of concrete work, in engine foundations, power plant walls and other work in connection with engineering projects. In almost every contract the greatest watchfulness has been necessary to insure the honest reinforcement of the structure. For some inexplicable reason the average concrete worker seems to consider the reinforcement used a sort of joke. I have seen men attempt to utilize three strands of barbed wire for a $\frac{3}{4}$ in. twisted bar. In many cases where 1 in. square bars have been distinctly specified an attempt has been made to substitute round bars with only three quarters the area. Many cases of failure in dams and retaining walls have been traced to such insufficient reinforcement.

My attention has been called by Professor Lawrence to the following ethical questions concerning the work of the engineer which I consider of the greatest importance.

Has a mechanical engineer a right to buy, invest in or sell stock in any company or corporation which may be direct-

ly or indirectly affected by his position, knowledge or influence?

Has a mechanical engineer a right to accept a commission either directly or indirectly on any material, equipment, machinery or supplies in use by the company he represents which could possibly affect his judgment?

Has a mechanical engineer any right to give out information regarding the plant to which he is giving his services to personal friends which might possibly act to the detriment, ultimately, of the concern that is employing him?

If we consider these questions at all seriously we must admit that we are confronted with a question of morals rather than ethics. The question then becomes: "Do you propose to use all your knowledge in the building up of the business that you are paid to exploit or will you use your profession to advance your own personal and private interests?"

A square deal in engineering means to me, first, a square deal to the person or company acting in the capacity of employer. In order to give this square deal, in the judgment of many of the leading engineers of the country, it is very much better that the graduating engineer should have no personal interest of any description whatever in the stock of the company or the earnings of the individual employing him. Personally I have, at times, purchased or otherwise acquired stock in companies employing me, but, in every case, I have found that it was a mistake on my part to become so interested. Self-interest is one of the most important factors to deal with and an engineer must be able to act absolutely without prejudice in order to render the best services possible in return for the compensation that he receives.

Now about giving out information concerning your work to outsiders. Here is a question that requires very careful discrimination. A man has a perfect right to feel proud of his work. Who of us do not? We are naturally anxious that our light should not be hid under a bushel; that our friends should know and appreciate what fine work we are doing, but even here let us bear in mind that our first duty is to the man that writes out the pay checks. It is so easy sometimes to start a conflagration and so terribly hard to put it out. Use most careful discrimination and if there is any doubt in your mind as to the propriety of mentioning business matters take my advice and—don't.

"Above all to thine own self be true; it must follow as the night the day thou canst not then be false to any man."

UNIVERSITY OF ILLINOIS

At a recent meeting of the University of Illinois Student Branch the following officers were elected for the next semester: R. C. Maley, president; L. Eslick, vice-president; E. B. Stout, secretary and D. E. Miller, treasurer.

This branch has just completed a very successful semester's work. Six meetings were held in which lectures and discussions of the following nature were given: Short Cuts in Computation, by Professor Goodenough; The Quarry St. Station of the Edison Commonwealth Company, Chicago, Ill., by E. C. Pierce; The Balancing of High Speed Engines by E. S. MacPherson; Coal Hauling Machinery, by L. Eslick and Saw Mill Machinery, by O. C. Hutchinson.

The big event of the semester was the "Open House" given by the society on the evening of October 23. The object of it was to bring the under-graduates of the University into closer touch with the engineering side of college life. All the laboratories, including the machine, forge and wood shops were thrown open to inspection while the different branches of mechanical engineering were being explained, demonstrated and illustrated by slides in the various departments. Souvenirs consisting of "I" buttons turned out by the wood shop, paper weights by the forge department and M. E. watch fobs of an artistic pattern molded in the foundry were presented to the visitors. In the steam laboratory each visitor was given a chance to make himself a set of indicator cards from the various steam and gas engines while the latter were running under full load. In one corner of the big steam laboratory was a complete power plant in operation which furnished power for the

Seroeco ventilating fan, and the dynamo which generated current for the large "A. S. M. E." automatic flashing sign. An ice machine in operation was demonstrated in another part of the laboratory and apparatus of various kinds were operated and explained to the visitors. There were 2000 people present.

UNIVERSITY OF KENTUCKY

At the December meeting of the University of Kentucky Student Branch, Prof. E. F. Parquhar spoke of the advantages of the engineer who has an extensive vocabulary at his disposal over the engineer with a limited vocabulary. He spoke in general of English being a prerequisite to the engineer.

At a meeting on January 14, Minott Brooke spoke at length of extravagances of the young engineer and introduced several methods of economy among resident engineers.

UNIVERSITY OF MAINE

At a meeting of the University of Maine Student Branch on January 22, Mr. Keppel Hall who is installing the Taylor system of Scientific Management at the Eastern Manufacturing Company's plant at Brewer, Maine, gave a talk on Scientific Management. The four main divisions that he emphasized were as follows: A close analysis of the work; close analysis of the workmen; putting the right man on the right job; making the management realize that the installation of Scientific Management was not for the sole purpose of profits for them.

UNIVERSITY OF MICHIGAN

At a meeting of the University of Michigan Student Branch on February 11, Wallace W. Tuttle was elected as chairman and M. S. Manwaring as secretary and treasurer of the Branch.

Prof. H. C. Anderson gave a general talk in which he mentioned several of the important branches of engineering a graduate mechanical engineer might possibly get into and some pertinent facts in connection with each of them and some good advice to the members.

UNIVERSITY OF MINNESOTA

The regular February meeting of the Minnesota Student Branch was held on February 11. Professor Shipley spoke on scientific shop management. He discussed the old military, the new Taylor and other systems now in use in various manufacturing establishments such as the Brown and Sharpe, the Tabor, and the Ford plants. He also took up in detail the various methods of compensating workmen.

UNIVERSITY OF MISSOURI

At a meeting of the University of Missouri Student Branch on January 28, the following officers were elected for the second semester: L. L. Leach, chairman; Troy Russell, secretary and treasurer; P. R. A. Nolting, corresponding secretary. A governing committee consisting of Prof. H. Wade Hibbard, honorary chairman, Prof. G. D. Newton, Stanley Goodman and J. C. Squires was appointed.

A special business meeting was held on February 5. At this meeting the terms of membership which were offered by the St. Louis Engineers' Club were accepted. The Club offers to members of student societies the privilege of Junior Membership at one-half the usual rates for initiation fee and annual dues. In addition to create interest among the student members, free associate membership carrying with it remission of initiation fee and dues for one year is offered to the student who shall present the best paper before the technical society of which he is a member.

The Engineers' Club in order to cooperate further with the student members and extend its field of usefulness offers to suggest speakers who would be willing to address student societies, to print in its May or June bulletin the names of members of student societies who desire to secure summer employment and to print in its Year Book a list of student societies and their officers. Further, the Club offers to participate annually in one joint meeting arranged by a student society or a group of cooperating societies, to grant to the

student members the facilities of its Library in exchange for a similar privilege to its own members in available university libraries, and to make an appropriation from time to time to assist a student in the making of an original research provided the recipient of such financial aid shall have the endorsement of the faculty of the institution with which he is connected and the approval of the Executive Committee of the Club. In such cases, the Club reserves the right to exclusive publication of the results of the investigation in its own Journal of Proceedings. The Club agrees to invite whenever possible, the members of the student societies to go with them on various excursions which it may have.

The resignation of the present corresponding secretary, P. R. A. Nolting was accepted. L. O. Royce has been elected in his place.

UNIVERSITY OF NEBRASKA

On January 12, at a meeting of the University of Nebraska Student Branch, L. F. Shedd of Chicago gave a very interesting lecture on the birth and progress of the Safety First and Prevent Injury Movements. He told how the railroad employees were taught the principles of the movement, and used stereopticon slides and motion pictures to show many of the careless practices of the employee and trespasser and their correction. Statisties were given to bring out the effects upon loss of life and limb that the movements are having.

At a meeting of the Branch on February 2, Dr. J. Stanley Welch, a graduate of the University of Nebraska and one of the greater medical and surgical authorities in the central west, gave a very interesting and practical lecture on First Aid to the Injured. He brought out very clearly those things which are of prime importance and the order in which assistance should be rendered to obtain the best results. Following the lecture, he gave a demonstration upon one of the students of the first aid methods of treatment of the most common injuries. The demonstration included the removal of a foreign substance from the eye and its treatment until a doctor could be obtained; bandaging and putting splints on a fracture; stopping excess loss of blood; treatment of a wound; artificial respiration; how to make and sterilize a bandage and the making of splints and many similar things which any one is liable to be called upon to do at any time.

EMPLOYMENT BULLETIN

Note: In Sending applications stamps should be enclosed for forwarding.

The Secretary considers it a special obligation and pleasant duty to be the medium of securing positions for members, and is pleased to receive requests both for positions and for men. The published notices of "men available" are from members of the Society. Notices are not repeated except upon special request. Names and records are kept on the office list three months, and if desired must be renewed at the end of such period. Copy for the Bulletin must be in hand before the 12th of the month.

POSITIONS AVAILABLE

041 Mechanical engineer for manufacturing plant employing 1200 men. Thorough technical training, some experience in machine shop work and experience in executive capacity. Location Massachusetts.

042 Concern manufacturing small electrical motors in quantities wants draftsman or clerk experienced in the standardization of product parts as well as tools; must be familiar with drafting room organization and systematic recording of standards. State age, references and salary. Name confidential, apply by letter.

043 Chief engineer charge of power plants and equipment, including four or five power houses, boiler plant, electric power station, etc. Location Delaware.

046 Mechanical engineer, experienced in soap factory construction and management, for position in vicinity of New York. Name confidential.

047 Four first-class, highly efficient engineers; the minimum salary, \$150 and expenses; positions will necessitate the men being on the road approximately seventy-five per cent of the time. Work consists of making power plant examinations, investigations, boiler tests, reports and recommendations. Prefer men with college education if possible, pleasant personality and tactful, as there will be constant call to handle difficult situations. Applicants must be familiar with boiler room economies and able to handle and conduct boiler tests, instructing the local men in such a way as to place the plant on the highest possible base of efficiency.

053 Young engineer in power plant work, steam engineering, and testing, for position with New Jersey concern.

054 Three draftsmen for service with a large mining company in Chili, South America. Two men must be first-class designers familiar with layout and detail work connected with a large milling and smelting plant. Third good steel designer. Must be unmarried and sign an agreement for three years. Salary starts day of departure from New York and all expenses paid to Chili and return. Living conditions at the plant are very good; climate temperate, pleasant and healthful. In application state age, experience, references and salary expected.

056 Firm of engineers and contractors having offices in New York and Chicago desires to add to present line agency for turbine or similar equipment.

061 Mechanical engineer for shop in middle west. Must have had practical shop experience and understand general machinery repairs, knowledge of boilers and engines and proper speeds and feeds of machine tools; also some knowledge of dies for pressing hot work. State age, experience, reference and salary.

MEN AVAILABLE

C-1 Associate-member, graduate engineer, six years teaching and four years general engineering experience desires position for the coming academic year in mechanical department of a technical school.

C-2 Junior, Stevens graduate, age 30, six years experience, desires position with contracting or constructing engineering firm, consulting engineer or architect.

C-3 Associate-member, technical graduate with broad experience in foundry, pattern shop, machine shop, drawing office and design, desires position of responsibility along similar lines. At present designing engineer for large machine tool concern. Eastern location preferred.

C-4 Member, age 39 married, with broad and thorough manufacturing experience from apprentice to agency manager in a large engineering corporation manufacturing steam and producer gas engines, producers and transmission machinery; with firm for nine years in the capacity of draftsman, designer, estimator, mechanical engineer, salesman and agency manager, also experienced in efficiency engineering, correspondent and advertising, desires position.

C-5 Junior member, technical graduate, 13 years railroad experience in motive power department as machinist, draftsman, boiler inspector, machine shop, car, roundhouse and general foreman, desires position as master mechanic or mechanical engineer.

C-6 Mechanical engineer with broad and varied experience available as purchasing engineer or as technical assistant in purchasing office.

C-7 Member, technical graduate, 12 years experience as designer, assistant superintendent and sales engineer with three well known engine building concerns, would consider responsible position with large engineering firm. At present employed.

C-8 Junior, graduate, broad experience in concrete materials, three years highway experience, now leveler, wishes position in foreign country.

C-9 Mechanical engineer, age 37, Stevens graduate 1900, experienced and resourceful, at present mechanical superintendent and assistant manager of large manufacturing plant desires position.

C-10 Member, technical graduate, wide training and experience in design of power plants and machinery, construction, maintenance and operation, purchasing engineering material, executive charge of all consulting engineering work, including building construction of all kinds, desires position as works manager or superintendent.

C-11 Junior, mechanical engineer, M. I. T. graduate, five years manufacturing experience, at present superintendent and purchasing agent of small concern, desires similar position in East with large firm preferably metal drawing and stamping.

C-12 Graduate engineer, six years experience factory maintenance and equipment work, desires position.

C-13 Member, technical graduate, with extended and unusual experience in shop, factory and power plant design, construction, equipment and operation, desires connection with high grade concern where the requirements call for engineering of ability and experience.

C-14 Junior, technical graduate in mechanical and electrical engineering, ten years experience in design, construction, operation and maintenance of power house and substations, high voltage electric design, piping design and layouts, etc., and building designs, desires position as power engineer, assistant superintendent of large mill, or designing engineer for large engineering firm or contractor.

C-15 Superintendent familiar with latest methods in machine shops and manufacturing plants, capable of demonstrating the output of machine tools and other equipment and getting the maximum production, can design tools and devise methods of producing interchangeable work at low cost.

C-16 Technical graduate, age 32, ten years experience factory engineering, including estimating, drafting, planning and economical production through cost control, desires position as superintendent, assistant to manager or factory engineer.

C-17 Superintendent or assistant, 11 years experience in executive capacity; thoroughly conversant with modern machine shop methods, expert designer of tools and labor saving devices. Exceptional experience in planning economical methods and qualified to handle manufacturing problems to increase production. Expert in pressed steel and punch press work.

C-18 Engineer, Stevens graduate, age 31, unmarried, capable manager, excellent designer, experienced writer of specifications, has just completed supervision of several large manufacturing plants, desires position as chief engineer for firm of industrial engineers and architects. Especially familiar with South, location immaterial.

C-19 Man with tool room and designing experience and familiar with metal working machine tools, special machinery for quantity production, tin can and paper container manufacture, is open for a position in the middle west. Can offer an improved design of a medium sized machine for manufacture.

C-20 Associate-member, technical education, age 31, experienced in shop, drawing room, as erecting foreman, has had charge of engine and boiler tests and with experience as tool designer on small work, desires position with consulting engineer or as salesman. Salary secondary consideration. Location immaterial.

C-21 Junior member, age 29, married, 12 years experience in design and construction of Diesel oil engines (European type), high grade automobile machinery and industrial plants, desires position.

C-22 Member, age 34, M. I. T. graduate, married, for past six years with leading engineers and architects in the East, designing steam power plants, heating and other piping systems and inspecting construction and equipment, at present employed as superintendent on construction and equipment of large mill and power plant, desires position along similar lines.

C-23 Member, age 33, with wide experience in design and construction of railway equipment, including modern steel passenger cars and trucks for heavy electric traction, desires position as assistant chief engineer or in similar capacity in charge of design or construction work along similar lines.

C-24 Junior member, University of Michigan graduate in mechanical and electrical engineering, age 29, unusual experience in efficiency work and design. Has held positions as superintendent, manager, efficiency engineer, and in charge of design. Some sales experience.

C-25 Junior, Cornell graduate, age 25, two years experience in fuel engineering and boiler testing, desires position in testing or experimental department of engineering concern. At present employed.

C-26 Member, graduate engineer with wide experience in efficiency engineering, also design and superintendence of light, heat and power plants, desires position with consulting engineer, architect or private concern. At present employed.

C-27 Member, graduate mechanical engineer, age 39, 20 years experience various engineering fields, inventive and executive ability, at present treasurer and general manager of engineering concern, desires to connect with responsible concern.

C-28 Member, technical graduate with 16 years railroad experience in motive power department as machinist, draftsman and mechanical engineer, desires similar position, or one as assistant superintendent, assistant superintendent of motive power, or motive power assistant to general manager or vice-president. Location immaterial.

C-29 M. I. T. graduate in mechanical and electrical engineering, age 32, married, broad and practical experience in power plants, locomotive repair shops and textile mills. Experience and ability could be applied in organization requiring man for chief engineer, production manager, electrical-mechanical or efficiency engineer, or for similar productive position.

C-30 Junior member, age 28, graduate mechanical engineer, five years practical experience, last two and one half years engineer of tests of large automobile company, desires position as assistant superintendent or engineer.

C-31 Mechanical and electrical engineer, 14 years experience in power plant and factory engineering, operation, maintenance and appraisal, also in handling men, systematic and economical operation, purchasing of equipment and material, recent experience in rubber and chemical works, desires position as works manager or supervising engineer of a manufacturing or industrial plant.

C-32 Junior, age 38, sales engineer, broad experience in handling high grade mechanical specialties, acquaintance in manufacturing and engineering fields, desires to represent manufacturers in east and middle west. At present employed.

C-33 Member, graduate M. I. T. in mechanical engineering, age 39, married, experienced in manufacture of ord-

nance-filled arms, shell and ammunition, design and construction of drydocks—wood, stone and floating, pumping plants, power houses and shops; acid and electrolytic refineries; wire and cable plants; reinforced concrete and general building construction with complete electrical and mechanical equipment for same; nine years general and seven years consulting engineering; position to be executive, superintendent or engineer of construction. Location preferred, Eastern Canada.

C-34 Junior, graduate mechanical engineer, age 26, over four years experience in power machinery and power station work including general inspection work on large hydro-electric power house construction; familiar with reinforced concrete and structural steel construction; considerable experience as draftsman, desires position on plant layout work or in the field. Location immaterial.

C-35 Lehigh University graduate in mechanical engineering, three years experience in design, shop work, superintending, construction and installation; can produce results at handling men, now maintenance engineer of factory employing 800, desires position with manufacturing, engineering, consulting or contracting firm.

C-36 Mechanical engineer, age 29, seven years practical experience in designing and drawing up specifications, also assistant engineer in superintending construction of power plants, water works, etc., desires position. At present employed.

C-37 Graduate M. I. T. in mechanical engineering, two years experience in maintenance of power equipment, plant and designing new factory building with large manufacturing concern, two years inspecting reinforced concrete and steel structures with irrigation project, familiar with reinforced concrete design, desires position with construction firm, or power and plant department of manufacturing concern.

C-38 Associate, age 33, college and technical education, seven years experience in charge of engineering correspondence and estimating, desires position as assistant to consulting engineer or to executive of corporation with good chance for advancement. Location New York or vicinity.

C-39 Graduate mechanical and electrical engineer, experienced in design and construction of machinery, building, manufacturing, systematizing, accounting, refrigeration, desires position in New York.

C-40 Member, sales engineer located in New York, good correspondent and estimator, broad acquaintance in manufacturing, engineering and expert field, has handled successfully well known accounts in New England and Eastern States, desires to negotiate with manufacturer wishing a reliable representative in New York who will accept the responsibility for the management and results.

ACCESSIONS TO THE LIBRARY

WITH COMMENTS BY THE LIBRARIAN

This list includes only accessions to the library of this Society. Lists of accessions to the libraries of the A. I. E. E. and A. I. M. E. can be secured on request from Calvin W. Rice, Secretary of Am. Soc. M. E.

AMERICAN SEWERAGE PRACTICE. Vol. I. Design of Sewers, Leonard Metcalf and H. P. Eddy. *New York, 1911.*

AUTOMOBILES INDUSTRIELS AVANT-TRAIN LATIL. Gift of Mission Française Ingenieurs aux Etats Unis.

CARNEGIE ENDOWMENT FOR INTERNATIONAL PEACE. Report of the International Commission to inquire into the Causes and Conduct of the Balkan Wars. *Washington, 1911.* Gift of C. W. Rice.

- THE COST OF POWER. G. B. Gould and C. W. Hubbard. *New York, 1914.* Gift of authors.
- DAS EISENBAHNWESEN DER SCHWEIZ. Placid Weissenbach. Band 2. *Zürich, 1914.*
- ETUDE SUR LES VEHICULES AUTOMOBILES A QUATRE ROUES MOTRICES, Charles Blum. *Paris, 1913.* Gift of Mission Française Ingenieurs aux Etats Unis.
- FIREARMS IN AMERICAN HISTORY. C. W. Sawyer. Vol. 11—The Revolver. *Boston, 1911.*
- DIE GRUNDGLEICHUNGEN DER MECHANIK. A. E. Haas. *Leipzig, 1911.*
- HANDBOOK OF CONSTRUCTION PLANT, ITS COST AND EFFICIENCY. R. T. Dana. *Chicago, 1911.*
- HAWAIIAN VOLCANO OBSERVATORY. Weekly Bulletins. vol. 2, no. 28-30. *1911.* Gift of C. W. Rice.
- HEAT TREATMENT OF STEEL. *New York, 1914.*
- HIGH-POWER GAS ENGINES. H. Dabbel, translated from the German by F. Wehrh. *New York, 1911.*
- INDUSTRIAL PLANTS. vol. 2. Gift of Chas. T. Main.
- AN INTRODUCTION TO THE MATHEMATICAL THEORY OF HEAT CONDUCTION WITH ENGINEERING AND GEOLOGICAL APPLICATIONS. L. R. Ingersoll and O. J. Zobel. *Boston, 1913.*
- DIE KOLBENPUMPEN EINSCHLIESSLICH DER FLUGEL UND ROTATIONS-PUMPEN. H. Berg. *Berlin, 1911.*
- LAKE SHIP YARD METHODS OF STEEL SHIP CONSTRUCTION. Robert Citty. *Cleveland, 1907.*
- LELAND STANFORD JUNIOR UNIVERSITY. Register, 1913-14. *1911.* Gift of A.S.M.E.
- DAS MASCHINEN-ZEICHNEN. A. Riedler. Ed. 2. *Berlin, 1913.*
- NATIONAL ASSOCIATION OF STATE UNIVERSITIES IN THE UNITED STATES OF AMERICA. Transactions and Proceedings, 1914. *Burlington, Vt., 1914.* Gift of Free Press Printing Co.
- ORGAN FÜR DIE FORTSCHRITTE DES EISENBAHNWESENS. Fünfzehnte Ergänzungsband. Zweckmässigkeit und Wirtschaftlichkeit des Eisenbetons. *Wiesbaden, 1911.*
- PERMEABILITY TESTS ON GRAVEL CONCRETE, MADE AT THE MATERIALS TESTING LABORATORY OF THE UNIVERSITY OF WISCONSIN. M. O. Withey. Reprinted from Journal of the Western Society of Engineers, Nov. 1914. Gift of author.
- POOR'S MANUAL OF RAILROADS. 1915. *New York, 1915.*
- SHERMAN, JAMES SCHOOLCRAFT. Memorial Addresses delivered at a joint session of the Senate and the House of Representatives of the U. S., Feb. 15, 1913. *Washington, 1913.* Gift of U. S. Senate.
- STEAM TURBINES. J. A. Moyer. Ed. 2. *New York, 1914.*
- DIE STEUERUNGEN DER VERBRENNUNGSKRAFTMASCHINEN. Julius Mazg. *Berlin, 1914.*
- TECHNISCHE MESSUNGEN BEI MASCHINEN-UNTERSUCHUNGEN UND IM BETRIEBE. A. Grunberg. Ed. 3. *Berlin, 1914.*
- UNIVERSAL SAFETY STANDARDS. Carl M. Hansen. Ed. 2. *New York, Universal Safety Standards Publishing Co., 1911.* Gift of publishers.
- The first of a series of handbooks compiled by Mr. Hansen under the auspices of the Workmen's Compensation Service Bureau of New York. It is devoted to the safeguarding of machine shops, not the "why" of safeguarding, but the "how." Safety devices are not only described, but illustrated by numerous plates, the safeguarding appliance being shown in the safety color, green. Safety appliances for the foundry are also shown.
- The great interest in these appliances, due partly to humanitarian considerations and partly to workmen's compensation legislation, is reflected in the great number of appliances pictured and described.
- W. P. C.
- VEREIN DEUTSCHER INGENIEURE. Das neue Vereinshaus in Berlin, 1914. Gift of Verein deutscher Ingenieure.
- GIFT OF WM. P. GERHARD
- THE PORT OF LOS ANGELES. Nov. 1, 1913.
- THE UNDERGROUND HAULAGE OF COAL BY WIRE ROPES. Wilhelm Hildenbrand. *Trenton, 1903.*
- EISENBAHN-BAUWESEN. A. T. Susemihl und E. Schubert. Ed. 6. *Wiesbaden, 1899.*
- GIFT OF ENGINEERING RECORD
- AMERICAN HIGHWAY ASSOCIATION. Proceedings of the American Road Congress. Pt. 11. *Atlantic City, 1912.*
- AMERICAN SOCIETY FOR TESTING MATERIALS. Reports of the Committee on Preservative Coatings for Structural Materials, 1903-13.

TRADE CATALOGUES

ATLAS BOLT & SCREW CO. *Cleveland, O.* A.S.M.E. standard for machine screws and machine screw nuts.

COEN CO., *San Francisco, Cal.* Catalogue no. 1. The "Coen" system of mechanical oil burning, 1914.

CRANE, WM. M. CO., *New York, N. Y.* "Vulcan" gas appliances. Catalogue.

FLANNERY BOLT CO. *Pittsburgh, Pa.* Staybolts. Oct. 1914.

GOLDSCHMIDT THERMIT CO. *New York, N. Y.* Thermit insert fully welded rail joint. (Pamphlet no. 39.) Thermit process of pipe welding. (Pamphlet no. 16. ed. 2.)

NEW YORK AIR BRAKE CO., *New York, N. Y.* Catalogue of air brake apparatus, September 1913.

PACKAGE MACHINERY CO. *Springfield, Mass.* Automatic machines for better wrapping of products. 31 pp.

SAFETY RULES. The Metropolitan West Side Elevated Railway, Northwestern Elevated Railroad, South Side Elevated Railroad, Chicago and Oak Park Elevated Railroad. ed. 2. Gift of Northwestern Elevated Railroad Co.

A STATESMAN'S OPPORTUNITY. An address before the Railway Business Association, by Fairfax Harrison. *New York, December 10, 1914.* Gift of Fairfax Harrison.

UNION IRON WORKS CO. *San Francisco, Cal.* Liquid fuel mechanical oil-burning system "Dahl" patents. 1913.

WASHINGTON ENGINE WORKS. *New York, N. Y.* "White" mechanical fuel oil burning system. 31 pp.

WATER TERMINAL AND TRANSFER FACILITIES. Letter from the Acting Secretary of War. U. S. House of Representatives, 63d Congress, 1st session, document no. 226. *Washington, 1913.* Gift of Thos. G. Patten.

THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS

ABRIDGED LIST OF OFFICERS AND COMMITTEE CHAIRMEN¹

JOHN A. BRASHEAR, *President*

CALVIN W. RICE, *Secretary*

Finance Committee, R. M. DIXON

House Committee, S. D. COLLETT

Library Committee (to be appointed)

Committee on Meetings, J. H. BARR

Committee on Membership, W. H. BOEHM

Publication Committee, C. I. EARLL

Public Relations Committee, M. L. COOKE

Research Committee, R. C. CARPENTER

Committee on Constitution and By-Laws, JESSE M. SMITH

LOCAL MEETINGS

Atlanta: Earl F. Scott

Boston: H. N. Dawes

Buffalo: David Bell

PUBLISHED MONTHLY BY

THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS

29 West Thirty-ninth Street, New York

PRICE 35 CENTS A COPY, \$3.00 A YEAR; TO MEMBERS AND AFFILIATES, 25 CENTS A COPY, \$2.00 A YEAR. POSTAGE TO
CANADA, 50 CENTS ADDITIONAL; TO FOREIGN COUNTRIES, \$1.00 ADDITIONAL

C 55. The Society as a body is not responsible for the statements of facts or opinions advanced in papers or discussions.

Entered as second-class matter, January 4, 1912, at the Postoffice, New York, N. Y., under the act of March 3, 1879

COMING MEETINGS OF THE SOCIETY

April 8, Buffalo, N. Y. Local Illustrated Meeting. Stereopticon views will be given showing interesting machinery and other views connected with engineering work which is being carried on in Buffalo by local manufacturers.

April 8, Worcester, Mass. Joint meeting of local members of the Am. Soc. M. E. with the graduates of Worcester Polytechnic Institute at Hotel Bancroft. Dinner at 7 o'clock followed by a stereopticon lecture on the Submarine, by R. H. M. Robinson, General Manager of the Lake Torpedo Boat Company. A committee for a local section of the Society will be appointed.

April 12, Philadelphia, Pa. Joint meeting with the American Institute of Electrical Engineers. Papers: Engine Driven vs. Turbine Driven Units in Small Capacities, by Albert C. Wood; and Washing and Cooling Air for Use with Electrical Apparatus, by an author to be announced.

April 13, New York City. Subject: Modern Electric Elevator and Elevator Problems, by David Linquist, Chief Engineer of Otis Elevator Company.

April 21, New Haven, Conn. Spring meeting, with afternoon and evening sessions. Subject: The Development of Machine Tools.

April 22, Buffalo, N. Y. Annual Meeting. Papers: Conservation of Niagara Falls Power, by H. B. Alverson, Superintendent of The Cataract Power & Conduit Company, and Patents, by C. W. Parker of Wilhelm and Parker.

April 23, Boston, Mass. Joint meeting under the auspices of the American Institute of Electrical Engineers.

THE SPRING MEETING

ARRANGEMENTS are progressing satisfactorily for the coming Spring Meeting which is to be held in Buffalo from the 22nd to the 25th of June. This date follows the commencement season at the colleges, so that many who are connected with the work of the technical schools of the country will be able to attend, where heretofore there could be only a very limited representation from any one college.

The local committees at Buffalo have all been appointed and are at work. The chairmen of these committees are as follows: General Committee, David Bell; Finance, D. W. Sowers; Reception, H. P. Parrock; Entertainment, David C. Howard; Hotel, W. H. Carrier; Printing and Publicity, John Younger. The entire membership of The American Society of Mechanical Engineers in Buffalo are to constitute the Reception Committee. The ladies of Buffalo are to appoint several of their number as patronesses to assist the Entertainment Committee at receptions and entertainments for the visiting ladies.

During the three days of the meeting there will be three periods for professional sessions, with probably four sessions, one of which will be in charge of the local engineers at Buffalo in accordance with the usual custom for the Spring Meeting. The papers for the several sessions are well in hand, the larger part of them already having been received by the Committee on Meetings, who regard them as of a very high order. Definite announcement of these will be made in the May issue of The Journal and printed copies will be available, free of cost, for all members who desire them in advance of the meeting.

This is the first meeting of the Society in Buffalo, although it held its convention at Niagara Falls in 1898. Naturally, Niagara Falls with its tremendous storehouse of energy, attracts the attention of engineers the world over; and especially in the electrical and chemical fields, because of the electro-chemical industries made possible there by the great quantity and low cost of power. The City of Buffalo, however, only 20 miles from Niagara Falls, with a population of 500,000, has many and diversified industries equally as in-

teresting to the mechanical engineer. Raw materials, coal, ores and lumber are brought by boat into Buffalo at minimum cost for transportation; and this, with the transmission of power from Niagara Falls, has made possible the great industrial development of the city.

The manufacturing plants include several large steel works, the largest of which is the Lackawanna Steel plant; blast furnaces, foundries, rolling mills for copper and brass, machine tool plants, machine shops manufacturing Diesel engines, steam pumps, steam engines, elevators, gas and gasoline engines, etc.; automobile plants, the new Curtis factory for aeroplanes, manufacturing for paints, oils, varnishes, rubber goods, hardware, paper board, etc. It is also a center for the brewing and flour milling industries.

Buffalo, besides, is a city set in a beautiful country with the added attractions of the lake and of Niagara Falls and is at its best in the month of June. Every opportunity will be afforded for the enjoyment of the city and its surroundings, both by the ladies of the party and the visiting engineers.

SAN FRANCISCO MEETINGS

Circulars have been sent to the entire membership relating to the International Engineering Congress for 1915 and the special train arrangements which have been provided.

The International Engineering Congress will be held September 20-25, 1915, in San Francisco, under the auspices of the American societies of civil, mining, mechanical, electrical and marine engineers. In connection with the Congress, The American Society of Mechanical Engineers will hold a meeting on September 16 and 17, the latter part of the week immediately preceding the week of the Congress, so as to enable its members to attend both the meeting of their own Society and of the Congress, and to visit the Panama-Pacific Exposition with the least possible expenditure of time.

During this period the headquarters of The American Society of Mechanical Engineers will be at the

Hotel Clift, with the management of which arrangements should be made direct and at as early a date as possible. A special train will leave New York on Thursday, September 9, arriving in San Francisco on Wednesday, September 15, with stops of several hours at Niagara Falls, Colorado Springs and the Grand Canon. Special arrangements are also planned for those in the South to go by way of New Orleans.

TRIP BY THE SECRETARY

In response to a number of invitations to visit the student engineering societies affiliated with this Society, the Secretary has recently visited Purdue University, Case School of Applied Science, Ohio State University, University of Cincinnati, State University of Kentucky, Virginia Polytechnic Institute, Georgia School of Technology and the Alabama Polytechnic Institute.

The Secretary was particularly pleased to visit Purdue as he had not been able to stop at the University for a number of years. It was not because of lack of interest that no visit had been made, but simply on account of the many demands on the Secretary's time which made more frequent trips impossible. On account of the prominent position which the University takes in research work, particularly in railroad engineering, which is one of the branches of engineering in which the Society takes great interest, there should be a strong section of the Society here and also an active student engineering society. The Secretary was particularly pleased to see on the bulletin boards an announcement of a joint meeting between the student societies of the Mechanical Engineers and of the Electrical Engineers. It is this spirit of coöperation which gives America its preëminence in the world in all activities. It is in this way that, while maintaining commendable rivalry, we omit competitive meetings.

At the University of Cincinnati splendid interest was shown. The men of the engineering society have to meet in the evening and, on account of being in the shops part of the time, the entire section could not meet on the same evening; consequently, the Secretary arranged to meet the students on two different evenings in order to greet them all. A photograph was taken of the members of the section and the section was encouraged to send it to the Society so that a reproduction of it might be given in The Journal.

The members of the Society in Cincinnati and vicinity had a dinner preceding the address in regard to the Society's work which was attended by Mr. Edward Hedden Worthington, a grandson of Henry R. Worthington, the founder of the Society, and also by George Hornung who has been a member of the Society for 30 years.

One of the interesting features in connection with the meeting in Cincinnati was the visit to the rooms of the Engineers Club. Previous to the organization of

local sections, the Engineers Club was practically inactive. At no time had as many as 15 of our members been members of the Club. As it is the policy of this Society to encourage in all cities the local engineering society and to make it the center of life for the engineering profession in that locality and to make the branches of the national societies contribute to the success of the local society, it was a source of great satisfaction to learn that Cincinnati had literally carried out the advice of the Society and had revived the Engineers Club with the result that there are now several hundred members, with 50 from our Society active in the organization, and with comfortable rooms in the center of the city open and available from early until late every day in the year.

At the State University of Kentucky, the Society enjoys the unique situation of having every Junior and Senior student in engineering a member of the student engineering society affiliated with The American Society of Mechanical Engineers. The mottos in the office of the dean are indicative of the theme of the address of the Secretary, namely, that the benefits for membership in the Society and in the student engineering societies are in proportion to the investment made by the student.

At Columbus splendid enthusiasm was shown by the men. Our student engineering society has as its officers the leaders in the college athletics and the same merit system prevails with regard to officers of sections as is required in athletics, namely, that no man may be an officer of a section with any demerits in the work of the University.

The Secretary does not want to fail to note the admirable library at Columbus and the enthusiasm of the assistant librarian to carry out the scheme proposed by the librarian of the Engineering Societies, to coöperate in the preparation of a finding list of engineering literature so that students and members in research work will be able to learn in what libraries they can secure sets of periodicals, Transactions and the important works generally.

At the Virginia Polytechnic Institute, Blacksburg, West Virginia, the Secretary was greeted by large posters announcing the meeting of the Society, distributed about the town. The meeting was attended by the entire student body and citizens generally. In the afternoon, the Secretary gave a separate address to the student branch. It was gratifying to have Dean Randolph state that six months after graduation he had joined the Society and that he had now been a member for 31 years and considered it the best investment of his life and a source of continual benefit. It should be remarked in this connection that, notwithstanding the fact that Blacksburg is a little out of the main line, when the interest of the members was aroused recently in the matter of bringing the benefits of membership in the Society to the attention of the engineering pro-

fession, Dean Randolph was successful in reaching a larger number than any other individual member.

At the Alabama Polytechnic Institute, Auburn, the Secretary was given the honor of addressing the entire student body in the presence of the President and the faculty. This was followed in the afternoon by a special address to the engineering students which was so well attended that the audience room was filled to overflowing and men were standing in the halls.

At the Georgia School of Technology similar enthusiasm was shown in the address given in the forenoon before the student body, which was followed by an address in the evening before the affiliated technical societies. A number of the students attended the evening meeting paying \$1.00 for the privilege as refreshments were served in connection with the meeting, and notwithstanding that there were three other student engagements scheduled for that evening.

In most places the merit system prevails and the work of the student engineering societies is being conducted on a high plane, direct or indirect credit in the regular school work being given for work in the student branch.

In each city where there are local members a meeting was also arranged. Great enthusiasm was shown, particularly at the universities in the South and at the meeting of the affiliated technical societies in Atlanta. The theme of the Secretary's remarks was the participation of the engineer in public affairs and involved a statement of what the engineer is doing and an encouragement to the engineers to take a great part from a sense of public duty and public service; also, that it is incumbent upon the engineer to acquaint the public with the work of the engineer. Following further statements about the work of the Society and its activities, there was an address illustrated by stereopticon views of the trip of the Society through Germany two years ago, with a description of the Deutsches Museum.

At Atlanta, members of the four national engineering societies, the American Society of Civil Engineers, the American Institute of Mining Engineers, The American Society of Mechanical Engineers and the American Institute of Electrical Engineers, and the American Chemical Society and the Engineering Society of the South have effected an organization where special emphasis is placed on service to the public, and in this respect so far as the Secretary is advised, this feature is unique in American engineering societies and highly to be commended. In other cities the engineers have gotten together in a splendid way, notably in St. Louis and Boston, where all meetings are cooperative; but in Atlanta they not only have cooperative meetings but, without any desire for position or remuneration, are placing themselves at the disposal of the city administration and in fact insisting on efficient, intelligent work being performed in the matter of smoke abatement, street construction, sewers and gar-

bage disposal, water works, etc., which is obviously the peculiar field of the engineer. In too many cities positions in these departments are filled by men with no peculiar fitness for the work.

HESS PRIZES FOR JUNIOR AND STUDENT MEMBERS

Announcement has already been made in The Journal and Year Book of the generous gift of Mr. Henry Hess, by which the income from \$2000 is available for the awarding of prizes for technical papers from Junior and Student Members. The committees of award for these prizes for the coming year have been appointed by the Council, and consist of the following members:

Junior Prizes

R. H. Fernald
Fred E. Rogers
George B. Brand

Student Prizes

F. R. Hutton
R. H. Fernald
D. S. Kimball

A statement is made in the first pages of this number of The Journal of the conditions governing the award of prizes and it is hoped that every Junior and Student Member will read these with care and that all who have valuable material which is available for a contribution to the Society will respond to the call and join in the friendly contest by sending such contributions to the Secretary of the Society so that they will be received on or before June 30, 1915.

COUNCIL NOTES

At the meeting of the Council on March 12, 1915, it was voted to approve the following amendment to the By-Laws:

All written reports of all committees shall be presented to the Council. Each written report of every committee must be approved in writing by at least a majority of the members of that committee, before it is presented to the Council. A member of a committee who disagrees with the action of a majority of that committee may express his disagreement over his signature either on the report of the committee or in a minority report. The minority report of any member of a committee, if offered, shall be presented at the same time that the report of that committee is presented to the Council.

All reports of committees must be first received by the Council who shall prescribe the manner in which they shall be presented to the Membership of the Society and be made public and printed.

It was voted that the portion of the Boiler Code report entitled "Rules for the Construction of Stationary Boilers and for Allowable Working Pressures," already received by the Council, be copyrighted as a preprint of Transactions. It was voted, also, that under the So-

ciety's copyright and without compensation to the Society, any legislative body be permitted to print these Rules and distribute officially for the state or municipality over its name.

It was voted that the members of the Council be requested to formulate suggestions for the conduct of professional committees and submit them to Mr. Henry Hess as Chairman of the Engineering Standards Committee, that this committee may have the suggestions in hand for drafting its code of rules.

The Secretary read the following resolution from the meeting of the New York Section held February 9, 1915:

"It is recommended that the Council be asked to appoint a committee to consider the question of the Society undertaking a digest of the material that has appeared in the publications of the Society."

In this connection, a communication from the American Gas Institute was presented requesting cooperation in the matter of a joint committee to obtain a standard system of classification of engineering knowledge.

VOTED: that the President appoint a committee of five to confer with the Committee of the American Gas Institute and that this committee of the Society also take under consideration the matter of a proposed digest of material that has appeared in the publications of the Society as suggested by the New York section.

VOTED: that R. H. Fernald, Fred E. Rogers and George B. Brand be appointed a committee on the Hess Prize for Junior Members and that F. R. Hutton, R. H. Fernald and D. S. Kimball be appointed a committee on the Hess Prize for Student Members.

CALVIN W. RICE, *Secretary*.

PRICE OF THE BOILER CODE

Since the last number of The Journal, in which was chronicled the completion of the report of the Boiler Code Committee on "Rules for Construction of Stationary Boilers and for Allowable Working Pressures," important action has been taken by the Society with regard to the price to be charged for the Boiler Code and in providing for the use of large editions by the legislative bodies of states and municipalities. The original price charged for copies of the Code was \$1.00 to members and \$1.50 to non-members. It had been thought that in view of the great amount of work that had been expended on the Code, not only by the Committee members but also by the office staff of the Society; and because of the great expense to which the Society had been in printing and handling the preliminary reports of the Committee (approximately \$6000), these prices were equitable and reasonable.

It is generally recognized, however, that the primary object of this report is not to reimburse the Society; on the contrary, the report has been prepared for the public good and it is undoubtedly destined to accomplish this end to a greater extent than any other pub-

lication which the Society has issued. Its greatest usefulness will not be attained until it becomes a standard in general use throughout the country, and the Society desires to do its utmost to bring about this most desirable accomplishment. It has therefore been decided to establish a scale of prices which shall not only be equitable to the membership of the Society, but attractive as well to legislative bodies.

For sales in limited numbers the same rate will be charged as for all of the reprints issued in pamphlet form by the Society, namely 5 cents per sixteen pages or fraction thereof, to members, and 10 cents to non-members, making the cost of the Code 40 cents to members and 80 cents to non-members on individual orders. For large editions for the use of legislative bodies and municipalities the price has been placed low enough to make it an inducement for ordering direct from the Society rather than to have it reprinted elsewhere, for one of the most important factors to be considered in the introduction of the Code is its accuracy. If the various legislative bodies that use the Code should have it printed by different printing establishments, with non-technical and indifferent proofreading, errors would be certain to creep in; while, on the other hand, any arrangement which would make possible the reproduction direct from the Society's type-plates of special editions that might be desired would insure accuracy. Hence the decision to name a price so low for quantity orders that printing from anything else than the Society's plates would in all probability be precluded. As a result the following schedule of prices has been put into effect:

PRICE LIST

For copies of the "Rules for the Construction of Stationary Boilers and for Allowable Pressures."

20 cents per copy in lots of 2000 or over.

30 cents per copy in lots of 1000 to 2000.

F.O.B. Printer, Lyons, N. Y.

40 cents per copy in lots less than 1000, delivered, to members of the Society (and to organizations when shipped to one address).

80 cents for individual orders delivered to non-members of the Society.

Special covers extra on orders of less than 2000.

An important decision in the administration of the Boiler Code was the action of the Council of the Society at its meeting of March 12, to copyright the Code as a reprint of Transactions. This was the result of a desire to protect the Code from undignified usage or inaccurate reproduction, it having been felt that such protection could not be gained in any other way. It was not the purpose, however, to restrict its distribution or limit its usefulness in the direction for which it was primarily intended. In order that legislative bodies might not be limited in any way by the copyright or in fact any restriction be placed on its distribution, a resolution was passed at the same meeting of the Council, as follows:

Resolved: that under the Society's copyright and without compensation to the Society, any legislative body should be permitted to print these Rules and to distribute them officially for the state or municipality over its name.

The completion of the report of the Boiler Code Committee, referred to in the preceding issue of The Journal, marked the inauguration of concerted efforts on the part of organizations of boiler manufacturers and others interested in uniform legislation, looking toward the introduction of the Boiler Code in various states. As announced in that issue, definite steps have been taken in this direction in Wisconsin, Indiana and Ohio. Since then similar action has been taken or proposed in a number of other states, including Michigan, Florida, Pennsylvania, New Jersey, Tennessee, and others. It is also of interest to note the commendatory action of the American Society of Agricultural Engineers at its recent annual meeting with respect to the Code, as evidenced in the following resolutions:

Resolved: that we, the American Society of Agricultural Engineers, assembled in annual meeting, do hereby unanimously approve of the efforts of the American Society of Mechanical Engineers to formulate a code of rules for the construction of steam boilers that may be used as a model by legislative bodies and thus promote uniformity.

Resolved: that we unanimously recommend the adoption of these uniform rules by the various states and municipalities having boiler legislation pending.

VISITS BY DELEGATIONS FROM TECHNICAL COLLEGES

At this time of the year, the Society is privileged to receive visits from colleges of groups of students who are on tour for the inspection of various plants previous to the Commencement exercises which come later in the season. Several such delegations have already called and others are expected for the current year.

One of the largest groups which has visited the Engineering Societies Building and Library is the Senior Class of electrical and mechanical engineers from the Sheffield Scientific School of Yale University. There were 120 students, each with his note-book for recording data connected with his trip. To this group, the librarian explained the manner in which the Library of the United Engineering Societies is endeavoring to serve the engineering public in all parts of this country, and even in other countries, by reference work, the translation of articles, and photographic reproduction of articles where complete transcripts are desired.

After inspecting the headquarters of the three founder societies in the building, the students all gathered in the auditorium for brief addresses by the secretaries of these societies, who spoke of the new and broader vision for the engineer who must in this day not only consider himself an engineer of things but of men; and in so doing have in mind that the greatest

results can be secured only by providing the best possible conditions for the workers who may come under their control and by giving their own services freely for the public good—in short, that service is the keynote of the success of the present day engineer.

FREDERICK WINSLOW TAYLOR

Frederick Winslow Taylor, Past-President of The American Society of Mechanical Engineers, died suddenly of pneumonia, in Philadelphia, on March 21.

Mr. Taylor was born in Germantown, Pa., in 1856. He had two years' schooling in Germany and France, and partially prepared for Harvard at Phillips Exeter Academy; but his eyesight became impaired and he had to withdraw from school. He determined, however, to get his education in another way and began an apprenticeship with William Sellers and Company, Philadelphia. In order to make as rapid progress as possible and to get some special advantages, he worked for less pay than the other apprentices, and in four years completed a journeyman's course both in the patternmaker's and the machinist's trade. When he finished his apprenticeship in 1878, times were so dull that he was unable to get work at either of his trades, and he entered the machine shop of the Midvale Steel Company as a laborer.

His first promotion was to the position of shop clerk, after which he was given charge of the toolroom. As head of the toolroom he saw the advantage of having all the shop tools ground by one man and instituted this reform, inventing the Taylor grinder for the purpose. From head of the toolroom he became successively gang boss, assistant foreman and then foreman of the machine shop. Next he became master mechanic in charge of repairs and maintenance of the works; then chief draftsman, and in 1884, chief engineer of the works, thus having advanced from laborer to chief engineer in six years.

Soon after he entered Midvale, young Taylor began to feel the need of a better understanding of the underlying principles of the science of engineering, and in 1880, while working ten hours a day, he began to study at night the engineering course of Stevens Institute of Technology, which he completed in 1883, when he received the degree of M.E. This remarkable accomplishment of passing the examinations of such a course as that of Stevens Institute of Technology in the short period of three years, with practically no assistance from any teacher, and while regularly at work, is striking evidence of his superior ability and capacity.

Mr. Taylor remained with the Midvale Steel Company until 1890, during which time he made many improvements in machinery and methods, and filled in a satisfactory manner the successive positions assigned to him. In his passage through the shops he had

studied the management and methods, and had developed his naturally keen powers of observation and ability to analyze and draw deductions. Whenever possible he made direct application of his deductions until the plant as a whole bore the imprint of his labor.

As no definite data were available as to what a mechanic should produce with a given tool and a given piece of work, he began systematic studies of the subject with the cooperation of the shop men, and as a result the output of many tools was increased 200 to 300 per cent with an increase of pay of 25 to 100 per cent to the workmen. Thus during this time he carefully observed and studied the general problem of

FREDERICK WINSLOW TAYLOR

securing higher labor and tool efficiencies and laid the foundation of what later became his specialty, "The development and application of the science of shop organization and management."

His work in constructive engineering was no less remarkable, for he designed the great steam hammer of the Midvale Steel Company, which was the largest successful hammer ever built in the United States, and the one steam hammer in all the world that could yield to the strain of a foul blow and by its elasticity recover its proper alignment.

In 1890 he left the Midvale Steel Company and became manager of The Manufacturing Investment Company, operating large paper mills in Maine, where he remained until his three year contract expired.

He then began, as consulting engineer, to introduce his principles of organization and management into various establishments about the country. During this period and in connection with this work he made many valuable improvements and inventions, a large number of which he patented.

In 1898 the Bethlehem Steel Company found that the output of their forge was much greater than the capacity of their machine shop to handle it. It was estimated that a new machine shop of sufficient capacity to keep up with the forge would cost one million dollars. At this juncture Mr. Taylor's success in producing increased shop efficiencies at other plants led the company to retain him to work at their problem.

Among the experiments made to increase the machine shop efficiency of the Bethlehem Steel Company were those on tool steel in conjunction with Mr. Maunsel White, leading to the discovery of the Taylor-White process of heat treatment, which increased the cutting capacity of tool steel 200 to 300 per cent. This process, and the tools treated by it, are now used in almost every machine shop in this country and abroad. They have revolutionized machine shop practice, and caused many radical changes in the machine tool industry. In the Bethlehem Steel Company's machine shop, where the discovery was made, the use of treated steel and the improved shop methods of Mr. Taylor resulted in such a remarkable increase in production that instead of an increase in the machine shop, an increase in the forge was necessary.

It was during his connection with the Bethlehem Steel Company that Mr. Taylor's ideas took concrete form on a large scale, and it is probable that during that time he first recognized the great possibilities of the broader application of the principles according to which he had been working, and realized the results that would be attained if these principles should become generally adopted throughout our industries. Having grasped the tremendous importance of this subject, Mr. Taylor decided, on leaving the Bethlehem Steel Company, to devote the remainder of his life to expounding these principles, which he now saw would create a new era in the industrial world.

He believed that he could do this to best advantage if he should make no charge for his work; and, having acquired a competency, he gave his services during the last fourteen years free to anybody who was sincerely desirous of carrying out his methods. He did more than this, for he not only invited everybody interested to his home, where he explained his methods to hundreds, and perhaps thousands, of people; but made extensive journeys at his own expense to lecture before interested bodies of people. It was on one of these trips that he caught the cold which resulted in his death.

Thus his work became known and appreciated not only all over this country, but in Europe and as far

as Japan. His books have been printed in almost all civilized countries, including Japan and China.

Although his qualities as an engineer command the admiration of all, his attributes as a man were quite as remarkable, and those who knew him best prized him even more as a man than as an engineer. His friends were quite as numerous among the workmen he came in contact with, as among his social equals; and those who had most to do with him freely testify to the benefit they received from his training and methods. Especially is this true with young men who have worked under him, and his success with them has been due to the fact that while an uncompromising and strenuous taskmaster, he recognized the value of time as an element in training, and was able to overlook the frequent personal issues which those who did not understand his methods insisted in raising at every turn. His remarkable ability to look beyond such issues and to see in them only incidents in the operation of broadening a man's view of work and duties, caused those who worked under him and understood his ideals to regard him as a friend who was always ready to give to his assistants full credit for their work.

He was Vice-President of The American Society of Mechanical Engineers in 1904 and 1905, and President in 1906, when he gave, as his presidential address, his exhaustive monograph, "On the Art of Cutting Metals," a treatise of 250 pages. Later he received the degree of Sc.D. from the University of Pennsylvania.

His written contributions were many; one of the earliest to come before the Society was his "Notes on Belting," presented in 1893. This paper contained the results of a long series of practical tests, and settled many contentions regarding the use and care of belts.

In 1895, he presented his paper on "A Piece-Rate System," in which he expounded the principles on which his system of management was subsequently based.

In 1903, he presented his celebrated paper on "Shop Management," in which he explained his methods in detail and the results to be derived from them.

In 1911, he published "The Principles of Scientific Management," which rounded out his theory of management.

He was joint author with Sanford E. Thompson of two works on concrete, "A Treatise on Concrete, Plain and Reinforced," and "Concrete Costs."

The funeral services for Dr. Taylor were held at the residence of his brother-in-law, Clarence M. Clark, Queen Lane Station, Philadelphia, when brief remarks of appreciation were made by James M. Dodge, Past-President, and Morris L. Cooke, Manager of the Society. The life and work of Dr. Taylor have received extended notice, both in the daily and technical press, and through the written comments of personal friends. Extracts from the remarks by Dr. Dodge and Mr. Cooke, and comments from other sources follow.

REMARKS BY JAMES M. DODGE

Dr. Frederick Winslow Taylor was a prophet, with honor in his own country and, at the same time, honored and respected in every civilized country of the globe. He was a remarkable student, a devoted husband, faithful friend, an inventor of the first rank, an engineer of resource, knowledge and keen perception, indefatigable in his work, unworshipping in his devotion to truth, modest and considerate. With this remarkable combination of temperament and learning he became the bearer of a message that is destined to make him recognized the world over as the emancipator of the worker and the employer; delivering the worker from the oppressive burdens of the old order and granting him freedom to do his best for himself and his family; and his employer from the necessity of being only the taskmaster and granting him freedom and opportunity to be the friend and co-worker of those associated with him.

Through his scientific investigations of the relations between employer and employee he was able to formulate a system which made it possible for both parties to realize that their interests, instead of being in irreconcilable conflict, were identical and interdependent, and that all questions between them could be settled by kindness, forbearance and patient investigation without resort to mistrust, suspicion, or antagonism. *He was the bearer of the only flag of truth that was ever carried upon the battle field of industrial strife.* Ignorance and prejudice have fired upon this flag, but it was never lowered, and now that the hand that carried it must relinquish its noble office, thousands of others will sustain it in its exalted position. I predict that it will never be lowered, and that the employer and the employee will both prosper under it as they have never prospered before, and with increasing respect, regard and solicitude for each other's welfare.

Many others have prayed for an industrial social millennium, expecting it to come from spiritual grace through lapse of time, but Dr. Taylor not only saw the possibilities of the future but he did more; he told in detail exactly how this long-hoped-for condition might be actually accomplished at once. The seed he has sown is springing up in thousands of places; the message he gave us is making hundreds, yes, even thousands of converts; the work he so ably started is based upon eternal truth and will partake of the lasting characteristics of its foundation.

REMARKS BY M. L. COOKE

So much stress has been put upon the practical accomplishments of Frederick W. Taylor that the great reach and sweep of his *spirit* has, except for the few, been almost submerged. All this lifetime of patient, tireless investigation; all the acuteness of his highly scientific mind; all the aspirations of a sensitive nature were bent on the one end of making human life a better thing to live. To this object he made the freest possible sacrifice of his fortune, his time and his health.

The strength of the great movement which Mr. Taylor originated lay very largely in the devotion which we in the ranks felt for our leader. We rarely thought to call him a great man, it seemed like such a surface observation to any one who ever saw him at work. But we were always conscious of his incessant struggle, of the long weary years of battling to make men have faith in themselves.

He had a wonderful capacity for friendliness, a capacity that could stretch across seven seas, and last a lifetime and reach the lowest man in the ranks. He taught us our mutual dependence and then proceeded to carry nearly all the load. He tinged all our work with idealism. Hear his own words: "I can no longer afford to work for money"; "all

our inventions and changes are made to produce human happiness"; "in all your relations do to the other fellow what you would have him do to you." Just a year ago, Father Serlilanges, preaching in Paris, said: "The love of God is the Taylor system of our inner life (*l'ameur de Dieu est le systéme Taylor de notre vie intérieure*)."¹ Mr. Taylor made us feel that there is nothing we cannot accomplish, and this without hurting our fellow men.

It was a part of the greatness of Mr. Taylor that he was not altogether concerned about the world's understanding of the greatness of his principles and motives. His loyal friends would do well to keep in mind his own words: "Patience, patience, and then more patience." His ideas forged ahead primarily because they were true and because they fitted in with the spirit of the time. But Taylor's "hanging on with his teeth," as he expressed it, and his willingness to stand alone when he was right, made them prevail.

Clear cut in his vision and keen in his judgments, fearless of criticism or misunderstanding, Frederick W. Taylor rang true in every act. He thought straight and spoke his mind with no uncertain sound and his speaking cleared the air of sophistries and evasions. No man who was ever honored by his friendship, sustained by his counsel, or upheld by his invincible spirit, can ever willingly set himself an easy task or be unwilling to tread the difficult way, so it be straight and clear.

FROM H. L. GANTT

Frederick Winslow Taylor's great contribution to the world's work was to substitute knowledge of human activities for opinion as a basis of action. His insistence that all industrial questions could be best answered by a scientific investigation was at first scoffed at by many of our industrial leaders, and it was nearly twenty years before he got much support. Now, however, at the end of thirty-five years, his persistence is bearing fruit so rapidly that the whole world is undergoing a revolution due to his ideas. His death cuts short the activities of a man who has had the welfare of his fellow men at heart, and who has devoted much of his life in trying to make clear the basis on which to establish industrial relations between employer and employee which shall be mutually satisfactory.

When he began his work all such relations were established by opinions. Today there are few industries in which fact has not supplanted many opinions. He had the feeling that waste was a crime, and that efficiency in work was a duty not only to ourselves and our employers, but to the community at large. His name will live as that of a man who could rise above individual cases and grasp general laws that would make for the happiness and prosperity of all.

If I were asked which piece of work more than any other illustrates his character as a man and an engineer, I would say the determination of the laws for cutting metals.

Finding himself balked at the outset of his career by a lack of knowledge on this subject, and realizing the great advantage that a knowledge of these laws would be to him and to the engineering profession in general, he determined to find out what they were. Suffice it to say that, although warned by his friends that he was attempting the impossible, and that for the first five years he scarcely made any real progress toward the desired end, he persisted in his work, to be rewarded after more than twenty years not only with the complete solution, but with the satisfaction of seeing the laws reduced to slide rules for their rapid application.

It was his persistent attempt to get uniformity in cutting tools that led, after nearly twenty years, to the discovery of the Taylor-White process of treating steel for cutting tools. This investigation involved at least fifty thousand experi-

ments and cost probably over one hundred thousand dollars; the fact that he was able to carry to a successful conclusion such a gigantic undertaking in the face of the lukewarm support of his friends, and the determined opposition of all others, is a testimonial to his strength of character which needs no comments.

The solution of this problem will always be connected with his name as one of the greatest pieces of scientific investigation of the nineteenth century.

His discovery, in connection with Maunsel White, of the Taylor-White process, is a piece of scientific investigation almost as remarkable, and in its results quite as far reaching, for it is the basis of treating all the modern high-speed tool steels, which have so much reduced the cost of cutting metals. This discovery was the natural result of his habit of making a thorough investigation of every problem with which he was confronted, and fully justifies his practice of carrying investigations to their logical conclusions even though such conclusions seem contrary to all previous experience.

FROM THE ENGINEERING NEWS

The sudden death of Frederick W. Taylor removes from among us one of the acknowledged leaders of the engineering profession. Although his death occurs at a comparatively early age, Mr. Taylor had fully completed the great task of his life. His great achievement was the introduction to the engineering profession and to the industrial world of what has come to be known, for want of a better name, as scientific management.

It has been said that this was not originated by Mr. Taylor. Other men before him had followed, to a greater or less extent, the practice of setting tasks for workmen and giving them instructions as to the best methods of performing the task. This fact, however, detracts little from the great credit due Mr. Taylor as the originator of what was in effect a revolution in manufacturing industry. What others had attempted in an isolated and partial way, he did in a thorough manner and with a clear view of the underlying principles involved and the enormous scope and possibilities of the new system. By his personal force and ability, moreover, he brought the new system into extended use in a short time. Had it lacked such a strong and powerful advocate, its development would surely have been far slower and more uncertain.

It is unfortunately true that the system which he originated has been widely misunderstood and misapplied. Beside the school of able engineers who worked with Taylor and followed his methods and in many cases improved upon them, a host of imitators has sprung up everywhere who have nearly made the word efficiency a by-word of contempt. Misuse of the Taylor system to drive workmen beyond their strength has been one of the causes that has brought against it the antagonism of the labor unions. It is worth while to say at this time that nothing aroused the righteous wrath of Taylor more than the misuse of his system by employers as a tool to get more out of their hands. He always believed and always urged that an essential feature to the success of his system was that the profit representing the increased efficiency resulting from its application should be equitably divided between the workers and the employer.

That many faults and imperfections have developed in the operation of Taylor's system and similar systems which imitators have brought forth, will be freely acknowledged by impartial observers. It remains true nevertheless that the system of scientific management which he to a large extent created is probably the greatest labor-saving instrument that has been developed in modern times.

THE SEE LIBRARY

Through the kindness of Mr. John Philp, Vice-President of the Glasgow Iron Works, New York, the Society has been the recipient of the collection of technical books forming the library of Horace See, who died December 14, 1909. Mr. See had given the library to Mr. Philp, but through the thoughtfulness of Mr. Philp the Society is now the owner of the books.

Mr. See was President of the Society in 1888, and was associated with the shipbuilding firm of William Cramp and Sons as designer and superintending engineer. It was under his leadership that the contracts for the first vessels of the "New Navy" of the United States were taken by his firm. He was also designing engineer for the transatlantic ships of the American Line.

The See Library is rich in the early works on naval architecture and the steam engine, especially the marine engine. It contains complete sets of several engineering periodicals and a large collection of pamphlets of a technical nature.

The collection will bear an appropriate special book-plate and will considerably strengthen the Society's contribution to the Library of the United Engineering Societies, where the collection will be catalogued and arranged.

UNITED ENGINEERING SOCIETY

REPORT OF TREASURER

TO THE BOARD OF TRUSTEES,

UNITED ENGINEERING SOCIETY.

I respectfully submit the following report of your Treasurer for the year ending December 31, 1914.

FINANCES

The Balance Sheet submitted herewith shows the physical property of the United Engineering Society, over and above the value of the building and the equity in the land, to consist of building equipment of a value of \$33,171.36, and library books \$1,698.75.

There was added to Furniture and Fixtures Account during the year 1914 an amount representing an expenditure of \$671.62, the principal items of which are: Typewriter for Library \$100, two reflectors \$50, cabinet \$60, mail box \$85, sign-boards \$47.38, hall runner \$37, and shades purchased during the year, \$207. In accordance with a resolution of the Board of Trustees, the total amount of furniture and fixtures at December 31, 1914, viz., \$6,467.08, has been written off.

The operations for the year 1914 resulted in a surplus of \$13,383.60, against which amount there has been charged by direction of the Board of Trustees, the Furniture and Fixtures Account amounting to \$6,467.08, also a transfer to Depreciation and Renewal Account of \$20,000, leaving a charge to Surplus Account of \$13,083.48, thus reducing the surplus of \$43,437.96 of January 1, 1911 to \$32,371.48.

The principal of the mortgage on the land held by Andrew Carnegie, Esq., amounting originally to \$540,000, has

been reduced by payments from the Land and Building Fund of the Founder Societies to \$59,000. Payment of \$29,000 was made during the year by the American Institute of Mining Engineers.

The present balances due from the Founder Societies are as follows: American Institute of Electrical Engineers, \$54,000, and American Institute of Mining Engineers \$5,000. The American Society of Mechanical Engineers has paid the full amount of its land indebtedness.

The gross operating expenses for the year 1914 were \$39,581.64, as compared with \$39,156.83 for the preceding year, showing an increase of \$424.81 for the year.

In accordance with a resolution of the Board at a meeting held on February 26, 1914, an appropriation of \$10,000 was made out of the surplus for the year 1913, and of this amount \$9,900 was invested in the purchase of \$10,000 Interborough Rapid Transit First Refunding 5% Bonds repayable 1966 at 99 as an addition to the Depreciation and Renewal Fund as provided for in the Founders Agreement, bringing the amount invested on account of this Fund to \$39,863.75.

Pursuant to a resolution of the Board of Trustees at a meeting held November 19, 1914, all interest earned by the investments on account of the Depreciation and Renewal Fund is to be added to this Fund. For the year 1914 this interest amounted to \$1,441.39, bringing the fund to \$41,441.39. A further resolution at this meeting directed that a transfer from this Fund of \$10,000 be made to "General Reserve Fund" to be available to take care of unforeseen fluctuations of income or outlay. The "Depreciation and Renewal Fund" to provide against gradual disappearance of this Society's assets now amounts to \$31,441.39.

A resolution passed by the Board November 19, 1914, provided that a sum not exceeding \$20,000 be transferred to Depreciation and Renewal Fund. On the advice of the Finance Committee acting under this resolution the entire sum of \$20,000 was set aside.

The following summary shows the reserve accounts and the investments thereto:

Depreciation and Renewal Fund.....	\$30,000.00
Add: Interest on invested funds, year 1914.....	1,441.39
Transfer for the year 1914	20,000.00
	<hr/>
	\$51,441.39
General Reserve Fund.....	10,000.00
	<hr/>
	\$61,441.39

The investments made on account of these funds are as follows:

INVESTMENT

\$10,000 Interborough Rapid Transit Bonds 1966.
5,000 N. Y. City 4½% Bonds 1917.
5,000 N. Y. City 4½% Bonds 1930 1960.
5,000 N. Y. City 4½% Bonds 1962.
5,000 Baltimore & Ohio P. Bonds 1948.
5,000 Delaware & Hudson P. Bonds 1943.
6,000 Southern Rwy. Co. P. Bonds 1956.
PURCHASES OF JAN. 11, 1915.
10,000 Chicago & Northwestern 5% Bonds 1987.
8,000 Northern Pacific 4½% Bonds 2017.
-
\$59,000

At the November meeting the Board of Trustees appointed the Astor Trust Company of New York City the custodian and attorney of the United Engineering Society

for the purpose of holding the securities and collecting the interest and dividends thereof, accordingly, the securities above listed have been deposited with the Astor Trust Company.

The assessments paid for the year 1914 by the Founder Societies, each apportioned one entire floor, were \$3,375, representing as last year a total expenditure by each Society, including interest on its full principal of mortgage on land of \$10,575, reduced in each case to the extent the Society may have paid off part or all of its mortgage share. The associate societies are assessed approximately \$10,000 for equivalent privileges, which shows that the Founder Societies still meet a little more than their proportion of the carrying charges for equivalent office space occupancy in the building. In accordance with a resolution passed by the Board of Trustees November 19, 1914, each Founder Society will be assessed monthly at the rate of \$12,000 per annum beginning January 1, 1915, and each society will be credited with 4 per cent upon the sum of its payments on account of its land mortgage, and a further credit for space released by any Founder Society.

BUILDING

Equipment. The Real Estate Equipment Account during the year 1914 has been increased to the extent of \$5,814, expended mainly for labor and material for additions and alterations on the 6th floor of the United Engineering Building and architects' fees in connection therewith.

Office Occupancy. There was on January 1, 1914 no unoccupied floor space (devoted to office space) in the building. There are now seventeen associate societies occupying office space in the building.

Meetings or Lectures. The record of the number of times the rooms were used during 1914 for meetings or lectures (not for office occupancy) is:

MEETING ROOM.

	1913.	1914.	Change.
Auditorium, 3d and 4th floors.....	69	76	7 more.
No. 1 Assembly Room, 5th floor.....	56	58	2 more.
No. 2 Assembly Room, 5th floor.....	129	94	35 less.
No. 3 Assembly Room, 5th floor.....	101	46	55 less.
No. 5 Lecture Room, 6th floor.....	10	0	10 less.
No. 8 Lecture Room, 6th floor.....	20	0	20 less.
Assembly Room 1201, 12th floor.....	18	53	35 more.
Committee Room (off foyer), 1st floor.....	10	18	8 more.
Total.....	413	345	68 less.

During the year 1914 the facilities of the building were used by 54 Societies holding a total of 251 meetings, with an attendance of 50,778 as compared with 56 Societies holding 309 meetings with an attendance of 63,348 during 1913.

LIBRARY

During the year 1914 there was added to the Library of the three Founder Societies and United Engineering Societies 3,616 volumes and pamphlets, of which 1,142 volumes and pamphlets were purchased at a cost of \$3,153.20. The total number of books and pamphlets at the end of the year was 57,861.

The attendance during the year was 13,512 as compared with 11,091 during 1913, an increase of 2,421.

One hundred and ninety-eight Searches have been made during the year. Correspondence has come from all over the world, and the questions are of great variety. Several hundred photographic reproductions have been made and

sent out. More than twelve hundred reference questions have been answered at the desk.

The Library receives more than 800 periodicals which are available through indexes for research purposes.

Respectfully submitted,

(Signed) JOS. STRUTHERS, Treas.

UNITED ENGINEERING SOCIETY

ANNUAL DINNER AT BOSTON

The Sixth Annual Engineers' Dinner was held at the Boston City Club, February 15, 1915, under the auspices of the Boston Society of Civil Engineers, The American Society of Mechanical Engineers and The American Institute of Electrical Engineers; the arrangements this year being handled by the Boston Society of Civil Engineers. There were 271 at the dinner and it was a very enthusiastic gathering. The toastmaster was James W. Rollins, president of Holbrook, Cabot & Rollins, Engineers and Contractors. An account of the meeting follows:

The first speaker of the evening was Harrison P. Eddy of the firm Metcalf & Eddy, Consulting Engineers, who is President of the Boston Society of Civil Engineers.

Mr. Eddy heartily welcomed the engineers present and spoke of the great benefit to be derived from these annual dinners.

The next speaker was Charles W. Baker, Editor in Chief of the Engineering News who in speaking of the opportunities for public service by the engineer referred to the work some of the engineering societies are doing in the way of following up the bills which are being presented to the State Legislatures. The committees who do this work have to make a report, the matter is then discussed and if possible a change in the bill is agitated if necessary. As one looks out on the world today, he sees two great forces struggling with each other, conservatism and radicalism. Thirty years ago conservatism was in the lead, but

since that time a most amazing change has taken place, and radicalism today is far in the lead but the great body of engineers should try to keep on the middle ground. The Child Labor Laws which are being agitated at the present day are causing quite an uproar all over the country. Intelligent men and women are on the platform in all the large centers speaking for more and more laws. The meaning of much of this is that every child should be prevented by law from performing any useful work before it reaches the age of 16 years. If this extreme ideal were carried into effect, we would produce a group of perfectly useless men and women. The enforced idleness which would take place would cause a great deal more harm than all the child labor now being performed. The boys and girls who were born and brought up on the New England hill sides and farms know what hard work means and in later years they know the joy of doing things.

Mr. Baker then touched upon the subject of government ownership and stated that probably within the next 25 years we should see the greater portion of the present day public utilities under government ownership. He said that he knew that some of the present day government methods are bad and that something must be done to correct them, and that it was up to engineers and the other men to give more time toward the correcting of the defects and take more interest in the affairs of government, city, state and national. Reforms should be put through so that these men can attain prominent positions and high rewards, and not lose their jobs every time there is a change of administration.

The next speaker was Chas. H. Eglee, manager dam and power dept. Aberthaw Construction Co. He said that the men today are losing their old ideas of standards and establishing new ones, which are better ones. He called attention to the various classes of engineers we have at the present day, the publicity engineer, mechanical engineer, hydraulic engineer, electrical engineer, mining engineer and steel engineer. Everything is trying to expand along new lines. The trade unions are trying to work as little as possible for as high a pay as possible in order that the working man may have an opportunity to improve himself; while on the other hand, the efficiency engineer with his stop watch is drifting in the direction of regarding a man as a machine. There we have the trade union on the one hand and the efficiency engineer on the other. The engineer, however, who is developing the finer qualities of manhood, giving each man an opportunity to expand as his individual qualifications make it possible, is the one who produces the productive man.

The next speaker was Capt. Robert W. Bartlett, the man who was the skipper of the ship Roosevelt when Peary discovered the North Pole and who later went with Steffansson up to the Arctic. He gave a number of personal experiences up in the North.

The Governor of the Commonwealth of Massachusetts, Hon. David I. Walsh, was the next speaker. He called attention to the great amount of good work the engineer could do by interesting himself in the affairs of the city and state, and spoke about the difficulty he had had in trying to induce engineering men to enter the public service. He hoped that the day would come when prominent engineers now in private practice would devote some of their time to the affairs of government.

APPLICATIONS FOR MEMBERSHIP

Members are requested to scrutinize with the utmost care the following list of candidates who have filed applications for membership in the Society. These are sub-divided according to the grades for which their age would qualify them and not with regard to professional qualifications, i. e., the age of those under the first heading would place them under either Member, Associate or Associate-Member, those in the next class under Associate-Member or Junior, while those in the third class are qualified for Junior grade only. The Membership Committee, and in turn the Council, urge the members to assume their share of the responsibility of receiving these candidates into the Membership by advising the Secretary promptly of any one whose eligibility for membership is in any way questioned. All correspondence in regard to such matters is strictly confidential and is solely for the good of the Society, which it is the duty of every member to promote. These candidates will be balloted upon by the Council unless objection is received before May 10, 1915.

NEW APPLICATIONS

FOR CONSIDERATION AS MEMBER, ASSOCIATE OR ASSOCIATE-MEMBER

- ALBERGER, ALVAN H., Pres., Alberger Gas Eng. Co., Buffalo, N. Y.
- ALLEN, ETHAN E., Engr., Abaca Products Co., Manila, P. I.
- ALVERSON, H. B., Supt. and Engr., The Cataract Pwr. & Conduit Co., Buffalo, N. Y.
- ARPE, JOHN G. H., Supt. of Pwr., Christian Moerlein Brewing Co., Cincinnati, Ohio.
- BAKER, ROBERT E., Secy. and Treas., Arthur G. McKee & Co., Cleveland, Ohio.
- BARLOW, FREDERIC C., with Phoenix Mfg. Co., Eau Claire, Wis.
- BARR, CLARENCE D., Ch. Engr., American Cast Iron Pipe Co., Birmingham, Ala.
- BEALE, HORACE A., JR., Pres., Parkesburg Iron Co., Parkesburg, Pa.
- BEEBE, LAWRENCE L., Asst. Mech. Engr., Off. Pub. Rds., U. S. Dept. of Agri., Washington, D. C.
- BELL, EDGAR D., Genl. Supt., St. Louis Elec. Terminal Ry. Co., St. Louis, Mo.
- BERGREN, AXEL E., Instr. in Steam and Gas Engrg., Univ. of Wisconsin, Madison, Wis.
- BEYER, JOHN J., Mgr. Fdy. Dept., The Otis Steel Co., Cleveland, Ohio.
- BOOTHMAN, DALE M., Ch. Draftsman, Shredded Wheat Co., Niagara Falls, N. Y.
- CAREY, THOMAS H., Supt. Engrg. and Insp. Dept., Globe Indemnity Co., New York.
- CARNEY, JOSEPH F., Mech. Supt., Greeley Square Hotel Co., New York.
- CARSON, CLARENCE, Cons. Engr., H. W. Johns-Manville Co., New York.
- CHESTER, THOMAS, Ch. Engr., American Blower Co., Detroit, Mich.
- COONEY, JAMES L., Supt., Cayuga Lake Plant, International Salt Co., Myers, N. Y.
- CORBETT, CHARLES F., Supt., City of Edmonton Filtration Plant, Alberta, Canada.
- DAILEY, FRED A., Pres. and Treas., Union Mch. Co., Contracting Engrs., St. Paul, Minn.
- DECKER, GEORGE A., Wks. Engr., The Warner & Swasey Co., Cleveland, Ohio.
- DEVINE, JOSEPH P., 1372 Clinton St., Buffalo, N. Y.
- DEWOLF, PAUL C., Asst. Treas., Brown & Sharpe Mfg. Co., Providence, R. I.
- DODGE, PARKER VAN P., Patent Solicitor and Mem. of Firm, Dodge & Sons, Washington, D. C.
- DURWARD, ERIC S., Asst. Supt., California Oilfields, Ltd., San Francisco, Cal.
- EYRE, THOMAS T., Asst. Prof. of Mech. Engrg., Purdue Univ., Lafayette, Ind.
- FERGUSON, DAVID, Mech. Engr., Pierce-Arrow Motor Car Co., Buffalo, N. Y.
- FLANDERS, WARREN B., Supt. of Pwr., Havana Elec. Rwy., La. & Pwr. Co., Havana, Cuba.
- FREEMAN, FREDERICK S., Supt. Pwr. Operation, Boston Elevated Ry. Co., Boston, Mass.
- FREEMAN, HERBERT A., Designing Engr., G. M. Davis Co., Chicago, Ill.
- GARDNER, ARCHIBALD, Asst. to Pres., Ambursen Co., New York.
- GOOD, PAUL E., Mech. Engr., Southwark Fdy. & Mch. Co., Philadelphia, Pa.
- GOODING, H. P., with A. B. Farquhar Co. Ltd., York Pa.
- HAGGETT, EDWARD D., Supervising Engr., Employers Mutual Ins. Co., New York.
- HAMILTON, ROBERT, Mgr., Robt. Hamilton & Co., Vancouver, B. C., Canada.
- HELMSTAEDTER, WILLIAM E., Mech. Engr., The Celluloid Co., Newark, N. J.
- HERMAN, SAMUEL J., Vice Pres. and Genl. Mgr., Diamond Pwr. Specialty Co., Detroit, Mich.
- HOWARD, LESLIE E., Mech. Engr. and Metallurgist, Simonds Mfg. Co., Lockport, N. Y.
- HOWE, CHARLES S., Pres., Case School of Applied Science, Cleveland, Ohio.
- JAMES, WILLIAM A., Ch. Engr., Lackawanna Steel Co., Buffalo, N. Y.
- INOKUTY, ARIYA, Prof. of Mech. Engrg., College of Engrg., Imperial Univ. of Tokyo, Japan.
- KING, WALTER A., Supt., Parker Bros. Gun Mfg. Co., Meriden, Conn.
- LACOMBE, CHARLES F., Cons. Engr., New York.
- LAMBUTH, LEONARD L., Asst. Supt., The United States Portland Cement Co., Concrete, Colo.
- LANE, GEORGE H., Secy. and Treas., C. J. Moberg, Inc., Mt. Vernon, N. Y.
- LEHN, HENRY C., with International Steam Pump Co., Buffalo, N. Y.
- MACDONALD, KARL, Ch. Mech. Engr., Clarksburg Water Wks. and Sewerage Board, Clarksburg, W. Va.
- MACKIE, EDWIN M., Asst. Engr., Pneumoelectric Mch. Co., SYRACUSE, N. Y.
- MELENDY, JESSE G., Supt., Buffalo Wks., General Chemical Co., Buffalo, N. Y.
- MERRILL, EDWIN R., Plant Engr., The Niles Tool Wks. Co., Hamilton, Ohio.
- MURPHY, JOSEPH E., Mgr. Mch. Dept., Eccles & Smith Co., Inc., Los Angeles, Cal.
- NASH, JAMES E., Supt., Worcester Salt Co., Silver Springs, N. Y.
- NEAL, JOHN R. H., with Robert Neal & Co., Buffalo, N. Y.
- NEWELL, FREDERICK H., Cons. Engr., U. S. Reclamation Service, Washington, D. C.
- NIELANDER, THEODORE, Supt. Mech. Dept., Andrews Steel Co., Newport, Ky.
- NOBLE, WARREN, Cons. Engr., The Wagner Elec. Mfg. Co., St. Louis, Mo.

OSWALD, JAMES N., Ch. Engr., Duquesne Light Co., Pittsburgh, Pa.

PELISSIER, LOUIS J., Genl. Foreman, Meh. Shop, Genl. Elec. Edison Lamp Wks., Harrison, N. J.

THE CLINKERING OF COAL

BY LIONEL S. MARKS, CAMBRIDGE, MASS.

Member of the Society

THERE is a growing feeling that the matter of clinkering ought to be taken care of when making contracts for coal and that specifications ought to include the melting temperature of the ash as indicating the clinkering characteristics of the coal.

The useful items in modern specifications for coal are the heat of combustion of the coal and its water and ash content. The latter permit calculation of the cost of handling inert matter when firing the coal and when disposing of the ashpit refuse. The volatile content of coal has an indirect interest in indicating its general nature but does not give any definite information about burning qualities. The important things about which specifications give no information are (a) as to the burning qualities of the coal (free burning or dead, caking or non-caking, etc.) and (b) the clinkering characteristics of the ash.

Before the subject of clinkering can be put upon a satisfactory basis, two kinds of measurement are necessary; (a) the determination of the extent to which the clinkering of a given coal is objectionable in actual use, and (b) the determination by a laboratory test of some characteristic of the ash which indicates the objectionableness of the clinkering. Some clinkers give very little trouble and are not particularly objectionable even when present in large amount. This is especially true of such clinkers as are non-adherent, easily broken up and easily removed. On the other hand, a small quantity of clinker which forms a pasty mass with the surrounding coal, or which runs on to the grate and freezes there as a strongly adherent but thin sheet, gives a very great deal of trouble and diminishes both the capacity and efficiency of a boiler considerably.

It is probable that the only reliable basis at present for determining the "objectionableness" of the clinker, is the judgment of fireroom observers. The writer has attempted to get a quantitative measurement by sifting the ashpit refuse into a number of selected sizes. In tests made with a Murphy stoker equipped with the usual clinker-breaker, the coals which gave most trouble were found to have the lowest percentage of smallest size clinker (less than 1 in.), and the highest percentage of the largest size clinker (greater than 2 in.). The differences between the percentages of the different sizes for good and poor coals is but small, so that the method cannot be relied on, but these observations have been used to confirm the judgment of the fire-room observers.

The only kind of laboratory test on coal ash which would seem to be of any real value is one in which the ash is subjected to such temperature as will cause it to melt either

The Friday morning Session of the Annual Meeting, December 1, 1911, was devoted to a number of papers upon miscellaneous subjects. Five of these appeared in abstract in the March Issue of The Journal, pages 159 to 179. The remaining paper of this group, The Clinkering of Coal by Lionel S. Marks, is here presented in abstract form together with abstracts of the discussion which followed.

wholly or in part. A number of attempts have been made to determine the melting temperature of an ash from its chemical analysis, but none of these attempts has been satisfactory, nor does it seem probable that this method will ever be available in view of the great complexity of the chemical constitution of coal ash.

That valuable indications may be obtained from a knowledge of

the iron and sulphur content of the coal or of its ash, is suggested by some recent tests of Palmenburg¹ which, as pointed out by Bergwyn,² appear to show the following results:

- a An ash containing less than 10 per cent of iron oxide (Fe_2O_3) does not fuse at a temperature below 2550 deg. Fahr.; an ash containing more than 20 per cent does not fuse at a temperature above 2550 deg. Fahr.; for an ash containing between 10 and 20 per cent the fusing temperature varies widely.
- b A coal containing less than 1 per cent of sulphur does not fuse at a temperature below 2550 deg. Fahr.; a coal containing more than 2 per cent does not fuse at a temperature above 2550 deg. Fahr.; for a coal containing between 1 and 2 per cent the fusing temperature varies widely.
- c A coal containing less than 3 per cent of iron oxide plus sulphur does not fuse below 2550 deg. Fahr.; and a coal containing more than 3 per cent does not fuse above 2550 deg. Fahr.

The determination of melting temperatures of coal ash is attended with many difficulties, the most important of which is in the definition of the melting temperature. When a coal ash is heated slowly, that one of its constituents which is the most fusible will be the first to melt. Its effect upon the rest of the ash will depend upon three factors: (a) the amount of that constituent; (b) its viscosity when melted; and (c) its chemical reaction on the remaining constituents. If there is much of this constituent the ash will become fluid to an extent which depends upon its viscosity. If the molten part is small in amount but very fluid, it may separate from the rest. With certain constituents, a eutectic may be formed whose melting temperature has but little relation to the melting temperatures of the constituents.

The best method of determining the extent to which melting has gone on at any given temperature, is probably that which has been used so successfully by the Geophysical Laboratory at Washington. In this method a small mass of the ash is kept at the desired temperature for a time sufficient to insure that the melting corresponding to that temperature is complete. The melt is then quenched and a thin

¹ Journal of Industrial and Engineering Chemistry, April, 1911.

² Journal of Industrial and Engineering Chemistry, August, 1911.

section of it is examined under the microscope. This method, however, may not be the most valuable for the determination of the clinkering characteristics of an ash.

There is another factor of great importance in connection with the behavior of molten coal ash, namely, its viscosity, which a satisfactory laboratory test for clinkering should indicate as well as melting temperature. The only method which has been used to any extent for this purpose, is really an imperfect method of determining the temperature at which the material has a standard viscosity. This is accomplished by heating the material in the form of a Seger cone of standard dimensions, at a standard rate, until it has bent to some standardized final form. The cone has usually been set up vertically. The rate of rise of temperature is usually taken as 2 deg. cent. (or 4 deg. fahr.) per minute, and the melting temperature is taken as that at which the tip of the cone touches the base. This method, it will be observed, does not really give a standard viscosity unless the time from the beginning of bending is the same in all cases. It should be noted also that the temperature of the cone increases as the bending goes on.

In tests by the writer with a standard rate of heating of 2 deg. cent. per minute, the time taken for the cone to bend to its final position from the beginning of bending, has varied

FIG. 1. APPEARANCE, AFTER FUSION, OF A CONE CONTAINING A VERY FLUID CONSTITUENT

from 10 to 80 minutes; the final viscosities in these two cases are obviously very different. It should be noted that even if this method gave standard viscosities, it would not necessarily give information of any value on clinkering. If it were true that all clinkers became troublesome when they reached a certain lower limit of viscosity, and if that particular viscosity were chosen as the standard, one might expect a close relation between laboratory and fireroom results. It has not, however, been shown that there is a lower limit of viscosity of the ash which cannot be exceeded without trouble from clinker, and moreover, in ashes whose most fusible constituents are very fluid the Seger cone method fails as indicated above.

Notwithstanding these inherent defects, the Seger cone method appears to merit further investigation, but an important modification in its use seems to be advisable. In the standard method the cones are placed vertically. This gives satisfactory results with the original Seger cones with many fire clays, but is often unsatisfactory with more complex mixtures. If the more fusible constituents are very fluid they run down to the base of the cone and may leave the apex apparently unchanged in a vertical or slightly inclined position (Fig. 1) until it disappears; that is, the cone never assumes the standard final shape. Furthermore, even cones which behave in the normal way may be difficult to observe since their direction of bending is not readily predictable or controllable without preliminary inclining or nicking. Mr. J. P. Sparrow of the New York Edison Company has suggested placing the cones horizontally with the apex projecting over the side of the support. This method has been

adopted by the writer as being more sensitive than the usual method and as giving indications which can be duplicated more accurately and are therefore more reliable. The temperatures noted in this method of testing are at the beginning of bending and when the apex of the cone points vertically downward.

The Seger cone method with the cone placed either vertically or horizontally, is used by a number of observers, but with an enormous diversity of the results obtained in different laboratories. This diversity results from differences in methods of testing, from differences in the definition of melting temperature, and also from the difficulties surrounding accurate pyrometric work. The writer has endeavored to ascertain the influence of the various factors which may affect the apparent melting temperature. The more important factors are (a) nature of the surrounding atmosphere; (b) size of the cone; (c) position of the cone; (d) nature of the binder; (e) rate of heating; (f) location of the cone in the furnace; and (g) method of support of the cone.

TABLE 1. INFLUENCE OF POSITION OF CONE ON MELTING TEMPERATURE

Date	MELTING TEMPERATURE DEG. CENT.		Difference Deg. Cent.

Seger No. 12 (full size)	1550	1300	50
Seger No. 16 (small size)	1450	1420	30

a *Nature of Surrounding Atmosphere.* Many of the writer's earlier tests were made with a Hoskins carbon resistance furnace in which the atmosphere is necessarily reducing and in which CO is always present. Preliminary tests on Seger cones gave results which agreed very closely with the readings of a Fery optical pyrometer. The melting temperature of the standard Seger cones was found to be unaffected by the nature of the surrounding atmosphere. With ash cones, however, it was found that the fusing temperatures, as observed in the Hoskins furnace, were in all cases much higher than those obtained in a Meker furnace in which an oxidizing atmosphere was maintained. The temperature in the Meker furnace was read by a Le Chatelier pyrometer which showed close agreement both with the Fery pyrometer and with the indications of Seger cones. The cones were all vertical, and the temperature differences ranged from 120 deg. to 255 deg. cent. (260 deg. to 459 deg. fahr.). It should be noted also that even the order of fusibility was changed in some cases when the at-

mosphere is changed, and that the lower the fusing temperature in an oxidizing atmosphere the greater is the increase in fusing temperature when changing to a reducing atmosphere. It is of prime importance that the cone should be surrounded by an oxidizing atmosphere.

- b Size of Cone.* The size of cone has an influence which is different for different materials. With Seger cones the difference is negligible. For example, a No. 16 Seger cone (17 mm base, 70 mm high) placed horizontally, has a melting temperature (initial and final bending) of 1355 to 1410 deg. cent.; when molded into the standard size of Seger cones of higher fusing temperature (8 mm base, 30 mm high), the result is 1355 to 1420 deg. cent. The size of cone adopted in the writer's tests was 11 mm base and 52 mm high. The ash of March 24 tested horizontally in a cone of this size gave melting temperature 1425-1450 deg. cent.; in a 13 mm base, 57 mm high cone, the temperature was 1400-1430 deg. cent. As is to be expected, the larger cones show a lower melting temperature but the difference is not great.
- c Position of Cone.* The melting temperature (complete bending) of a horizontal cone is always less than for a vertical cone, as shown by Table 1. The difference varies considerably and is less with the more fluid melts. The cones of March 5 or February 10 showed a particularly fluid melt.
- d Nature of Binder.* The ash is usually mixed with a 10 per cent solution of dextrin before molding into cones. It was found, however, that water alone was satisfactory if the cones are not dried much before putting in the furnace. The effect of adding dextrin is generally negligible, but sometimes it increases the apparent fusing temperature (complete bending) by as much as 10 deg. cent.
- e The Rate of Heating Cones* has a marked effect on the apparent fusing temperature. Any increase in the rate results in increased lag of the pyrometer (Le Chatelier type with porcelain tube), and causes an apparent decrease in the melting temperature. Tests on the ash for February 4 and February 6 showed melting temperatures (complete bending) which were 40 deg. and 35 deg. cent. respectively lower, with 6 deg. cent. increase per minute, than with 2 deg. cent. increase per minute.
- f The Location of the Cone in the furnace* is important; it should be as close to the pyrometric element as possible. The temperature at the front of a No. 29 Meker furnace was found to be about 20 deg. cent. lower than that in the middle of the muffle. An additional door plate reduced this difference.
- g The Cone must be Supported* on material which is unaffected by the highest temperature reached and which does not react chemically on the ash cones. Plates of fused quartz have proved very satisfactory in the writer's tests. They have to be supported in such a way as to permit circulation of the gases below them so that they shall have the same temperature as the rest of the muffle.

Another point of importance is the complete incineration of the ash before it is made into a cone. An appreciable amount of carbon remaining unburned tends to increase the apparent fusing temperature.

The arrangement of apparatus finally used in the writer's tests is shown in Fig. 2. Holes were made in the back of the furnace for the insertion of the pyrometer, and in front for observation and for the insertion of a quartz tube through which a stream of air was introduced into the muffle to ensure an oxidizing atmosphere. The furnace was heated rapidly to within about 200 deg. cent. of the expected fusing temperature and the rate was then reduced to 2 deg. cent. per min., and was kept there. The observation hole was plugged up except when in use. Observations were made through very dark blue glass at $2\frac{1}{2}$ min. intervals. The horizontal cones were supported only so far as was necessary for balance.

In order to find out whether fusing temperatures as determined by the method outlined above, have any relation to the amount of clinker trouble experienced in burning the coal, a series of tests was carried out on a boiler equipped with a Murphy Stoker at the L Street plant of the Edison Electric Illuminating Company of Boston. Fourteen tests were made, each of 24 hours duration, with 10 different coals; 5 of the tests were made with one coal, and 1 test with each

FIG. 2 ARRANGEMENT OF APPARATUS USED IN TESTS

of the 9 remaining coals. Table 2 gives the results of tests of the ash and a statement of the extent of the clinkering for each of these tests.

It will be seen that there is a general relation between the two but that it is not definite enough to be of much practical use. The coals giving the three lowest fusing temperatures (February 10, March 5, April 8) are also those giving the maximum clinker trouble. Those ashes with a final fusing temperature of 1400 deg. cent. (2552 deg. Fahr.) or higher, gave little trouble, but the ash of February 6, which melted at 1380 deg. cent. (2516 deg. Fahr.) gave little trouble, while those of February 13 and March 13 which melted at 1395 deg. cent. (2543 deg. Fahr.) gave much trouble. The most troublesome clinkers (February 10, March 5 and April 8) had final melting temperatures of 1370 to 1375 deg. cent. (2498 to 2507 deg. Fahr.) which is practically the same as the temperature for the good coal of February 6. It would appear then, that the final melting temperature cannot be taken as a criterion in the range from 1380 to 1400 deg. cent. (2516 to 2552 deg. Fahr.) and the inference is that the uncertain region extends over a still wider temperature range. It is probably true that final fusing temperatures below 1350 deg. cent. (2462 deg. Fahr.) show a coal which would give clinker trouble under the conditions of the L Street Station, and that temperatures above 1420

deg. cent. (2588 deg. fahr.) indicate a coal comparatively free from such trouble, but further investigation would be necessary to establish that fact. The important thing, however, from the point of view of coal specifications, is that the tests of the ash of February 3, 4, 5 and 6, when the regular station coal was used which gave a minimum of clinker trouble, yield results which fall in the doubtful region and would therefore be rejected in coal specifications based on fusing temperatures alone.

Additional indications of the liability to clinker trouble may be obtained from the range of temperature during bending and from the appearance of the bent cone. The cones of the ash which gave most trouble had a very fluid constituent which ran down to the tip of the cone and also upon the supporting plate and gave the appearance shown in Fig. 3; those giving least trouble were as in Fig. 4. It would appear that the most fusible constituents will separate from the rest of the cone when it is very fluid, leaving a skeleton

FIG. 3 FUSED CONE WITH VERY FLUID CONSTITUENT

FIG. 4 NORMAL FUSED CONE

which does not bend until its own fusing temperature is reached; that is, with the kind of ash which gives most trouble, the Seger cone method fails as a result of the separation of the more fusible from the less fusible constituents.

It is possible to accept the appearance of the bent cone as a partial indication of the clinkering behavior, and it may be possible to predict the behavior of an ash from that indication combined with the fusing temperature. The range of temperature during bending may also possibly be used. The range varies from 15 deg. to 55 deg. cent. in the tests given in Table 1; in other tests by the writer it has amounted to as much as 140 deg. cent. There seems to be a very close

relation between this range and the viscosity of the melted cone. The ash cones of February 10 and March 5 show the smallest range and they also show greater fluidity (Fig. 3) than any of the other cones. It should be noted, however, that there is a liability to error in observing the initial and final bending temperatures, which is not less than 10 deg. cent. so that an observed range of temperature of 30 deg. may actually be anywhere from 10 deg. to 50 deg. cent.; it is necessary to make several determinations in order to get the range with reasonable certainty. The appearance of the melted cone is consequently more valuable than the range of fusing temperature.

The investigations of the writer seem to show that under the conditions of combustion at the L Street plant of the Edison Electric Illuminating Company of Boston a coal with a fusing temperature (final bending) below about 1400 deg. cent. (2550 deg. fahr.) will probably give trouble if the ash has a fluid constituent; whereas, it will not give trouble above about 1380 deg. cent. (2516 deg. fahr.) if the ash is viscous. This conclusion would require further investigation with many other coals before it could be accepted even for this particular plant; naturally it cannot be applied to plants with different operating conditions.

DISCUSSION

F. C. HUBLEY,¹ referring to the author's statement that a satisfactory laboratory test for clinkering should indicate viscosity as well as melting temperature, said it would probably be well to go further and state that such a test should indicate viscosity at any temperature throughout the softening range, and furthermore it should be of such a positive and definite nature that results from the same sample but from different laboratories, would agree closely. In searching for a more definite form of test than the various cone methods present, the writer finally adopted a test in which the collapse of an ash cylinder, under a slight vertical pressure, due to softening, is plotted against increasing temperature to form a curve, the shape and extent of which apparently present a complete picture of the nature and position of the softening range of the ash under test. The ash cylinder is formed without the use of a binder, from the completely incinerated pulverized ash, in a press exerting 30,000 lb. pressure per sq. in. on the cylinder.

Mr. Hubley gave a description of a fusimeter, which after experimenting in the construction of various designs of this instrument, has been adopted in the form shown in Fig. 5, as being best suited, mechanically speaking, to carry out the proposed fusion tests. A test pellet *W* is held centrally in the furnace *A* by carbon rods *C* and *D* which are ordinary are lamp carbons $\frac{1}{2}$ in. in diameter. Rod *D* is held by a clamp *E* to the bottom of the furnace body and rod *C* and weights *L* and *N* are free to move vertically, carrying in this particular instrument, weights designed to exert a unit pressure of 1.5 lb. per sq. in. on the pellet. This rod is held on the center line of the instrument by four guide wheels and a silk cord over a pivoted pulley connects this rod and weights with a counter weight *P*. A pointer *V* is fixed to this pivoted pulley and indicates on a scale on plate *U*; the pulley is 1 in. in diameter and the pointer 6 in. long, so that any vertical movement of the carbon

TABLE 2 MELTING TEMPERATURE OF ASH AND FIRE ROOM RECORD OF CLINKERING

Date	MELTING TEMPERATURES DEG. CENT. (FAHR.)		Amount and Character of Clinker
	Initial and Final Bending	Range	
Feb. 3	1350-1395 (2462-2543)	45 (81)	Light
4	1360-1400 (2480-2552)	40 (72)	Light
5	1360-1400 (2480-2552)	40 (72)	Light
6	1340-1380 (2441-2516)	40 (72)	Light
10	1360-1375 (2480-2505)	15 (27)	Hard, excessive; 50 per cent of grate
13	1350-1395 (2462-2543)	45 (81)	Excessive to moderate; large clinker
Mar. 3	1370-1420 (2498-2588)	50 (90)	Not much, but very hard and isolated
5	1350-1370 (2462-2498)	20 (36)	Excessive; 75 per cent of grate
11	1355-1380 (2471-2516)	25 (45)	Heavy
13	1340-1395 (2444-2543)	55 (99)	Heavy
17	1430-1480 (2606-2696)	50 (90)	Light
24	1420-1450 (2588-2642)	30 (54)	Very little
26	1500 (2732)		Light, hard
Apr. 8	1335-1370 (2435-2498)	35 (63)	Excessive; very hard, 18 to 20 in. in <i>V</i> and thick

In experiments carried out by the writer, a gas-heated

FIG. 5 ELEVATION AND PLAN OF FUSIOMETER

Mr. Hubley explained the method of making the test and stated that, with the ash pellet and carbons in the position shown, and the pointer P adjusted midway between zero and 1.00 on the scale, the furnace is gradually heated at the rate of from 50 to 100 deg. Fahr. per minute, simultaneous temperature and scale readings being made at one-half minute intervals. As the heat is increased negative movement of the pointer will indicate carbon expansion up to a temperature where first softening of the ash pellet is indicated by a positive movement of the pointer. The experiment is continued till final collapse of the pellet is indicated on the scale. These results if plotted, the temperatures as abscissae and the pointer movement as ordinates, produce a curve, an ordinate of which at any point is a measure of the relative rate of softening of the ash pellet at that temperature.

FIG. 6. ASD FUSION TESTS ON MIDDLE PENNSYLVANIA COALS
WITH FUSIOMETER

The other type of ash fusion is a short range spongy porous formation of low viscosity, which if it does not occur too low on the temperature scale, can be handled with ease in the boiler fires. From a comparison of boiler house results with a large number of tests made, the fusimeter curve for this type of fusion appears to be distinguished by a most decided downward dip in the curve just prior to final softening.

Mr. Hubley pointed out the fact that the term "fusing point" is misleading and indeterminate, while "fusing

range" of a substance can be determined with exactitude. For purposes of relative comparison, however, an arbitrary point in the fusing range may be selected and called the "fusing point" of the ash. For this point in the case of the fusimeter results, he suggests the temperature at which the pellet has collapsed due to softening, to one-half of its original height.

Mr. Hubley discussed several curves developed from a number of ash tests, using this instrument, together with boiler house reports in regard to the nature and extent of clinker formed under actual operating conditions. He showed tests of two samples that indicated a wide variation in the viscosity of melt between ashes fusing at approximately the same temperature, and pointed out the futility of using only the relative ash "fusing points" to grade

FIG. 7. FUSING RANGE OF ASH CONSTITUENTS USING FUSIMETER

coals as to their probable freedom from clinkering trouble, without considering also viscosity and length of softening range (see Fig. 6). One of these coals formed a porous clinker easily broken up and the other a close gummy clinker difficult to remove from the firebox. A number of similar graphical records of tests were shown that clearly indicated the characteristics of the coals tested.

Mr. Hubley showed in Fig. 7 curves for calcium sulphate and the red oxide of iron that are interesting, since they represent, in shape, the two extremes of coal ash fusion. Of the total number of ash samples tested by this method, a large percentage of those melting between 2100 and 2500 deg. Fahr. show indications in varying degree of the dip in the calcium sulphate curve. Also, a coal ash producing a fusion curve similar to that of the sulphate, shows a low viscosity of melt and will produce a porous brittle clinker easily broken up and removed from the fire box; while an ash producing a curve similar to the ferrie oxide fusion, indicates high viscosity and the production of a tough gummy clinker difficult to break up and remove from the fire box.

He showed that the first type of fusion, while causing no excessive delay at cleaning periods, is productive of dirty fire and a high percentage loss of carbon in the ash pits.

The second type not only causes delay at cleaning periods, but increases the wear on the grate bars and brick work, in addition to cutting down the capacity and efficiency of the boiler as a whole. One of the effects of this type of fusion is to arch over the back grates on a stoker, preventing the admission of air necessary to economically burn down a fire preparatory to cleaning.

The expansion of a pellet of calcium sulphate, between 2100 and 2350 deg. Fahr. or prior to the melting point, would indicate the evolution and release of a gas between these temperatures. He is still seeking an explanation of this occurrence, since this curve was reproduced a number of times both in shape and position on the temperature scale; first in the presence of reducing agents and later with the carbon rods covered with platinum ferrules and an excess of air in the furnace gases.

He referred to Fig. 8, which shows fusimeter tests on a three-car shipment of coal from a certain mine and illustrates a number of important points bearing on the clinker problem.

First. Curves 1 and 2 show the accuracy which may be obtained on duplicate samples from the same ash. He

FIG. 8. SOFTENING RANGE OF BITUMINOUS COAL ASHES FROM FUEL USED IN TAYLOR STOKERS

believes that if complete incineration and thorough pulverizing and mixing of the ash sample occurs previous to testing, the accuracy shown in Curves 1 and 2 and in some of the previous illustrations may be obtained in each case. It follows therefore that two different laboratories, both using this method, could be expected to show a correspondingly close agreement in results obtained, a circumstance which appears to be conspicuously lacking where modifications of the Seger cone method are used. This is an important point if the clinkering characteristic of fuel is to be regulated by a specification based on the method of determination of softening temperature.

Second. Fig. 8 also illustrates that three cars of coal from the same mine, although showing the most remarkable uniformity as to proximate analysis, sulphur content and heating value, will vary considerably as to fusibility of ash. It has been found at times that the ash in the roof or large partings in a vein will vary considerably in fusibility with the true ash of the coal, but in this case it would appear,

from the uniformly low ash obtained in each car, that in this vein or mine the true ash itself varied in fusibility.

Third. As actually tested, these three cars were used in Taylor Stokers with Rust boilers operating at 180 per cent of rated capacity. At this rate, fuel bed temperatures as high as 2800 deg. Fahr. have been observed with the Ferry radiation pyrometer, with an average of over 2700 deg. The boiler room reported as follows: "This coal proved to be unsatisfactory inasmuch as it clinkered to a troublesome extent. Coal contained in Test No. 7973 appeared to make a much harder clinker than either of the other cars." It would appear therefore that, knowing the approximate fuel bed temperatures under which this coal was to be consumed, the degree of probable clinker trouble in using this fuel under these load conditions could have been predicted from the curves in Fig. 8. The fact that a porous easily removed clinker was not formed (as would be ordinarily indicated by the dip in the curves previous to melting) is probably due to the high fuel bed temperature at which this fuel was consumed, a temperature far above the final melting temperature of any one of these ash samples. In other words, had fuels represented by Curves 3 and 4 been consumed at fuel bed temperatures of 2500 deg. Fahr. or under, a porous easily removed clinker would probably have been formed. The same can be said of fuel represented by Curves 1 and 2 for fuel bed temperatures of 2300 deg. Fahr. or under. For Babcock & Wilcox boilers with Roney Stokers, 2500 deg. corresponds to a load of approximately 150 per cent of rating and 2300 deg. to 110 per cent of rating.

It has often been noted, in a boiler fire room, that in burning a fuel which produced a not too troublesome clinker, if for one reason or another the fire is not thoroughly cleaned at one fire-cleaning period, the clinker not removed at this period will give excessive trouble in removal at the next succeeding period. One sample shown could give trouble of this nature, not because of the reduced temperature at which this ash re-fuses but due to a change in viscosity of the re-fused mass.

Basing an opinion on this form of test, the writer suggests the following specification: The pellet shall not have collapsed due to softening, to more than one-half of the original height at a temperature T , and in addition, shall not show a collapse of more than one-eighth of the original height due to softening at a temperature 300 deg. Fahr. under temperature T . The first part of this specification will limit the final fusion, while the second part is intended to control viscosity and avoid the sloping curve shown in Tests No. 7124, Fig. 7 and 7201, Fig. 6.

Referring to Fig. 9, the position of the line A-A or the fixing of temperature T must vary for plant conditions. It is obvious that the buying field for steam coal will be restricted or broadened according as the temperature T is raised or lowered, so that the fixing of this temperature must be governed by the value which a plant management places on loss of boiler capacity, and risk of steam failure against the saving made in purchasing the cheaper fuel.

O. W. PALMBERG¹ offered a method of testing which he follows and which he has found to give satisfactory results when comparing laboratory tests with results as obtained in practice. He uses a gas muffle furnace heated with a double blast Meker burner and by this means can

attain temperatures ranging as high as 3000 deg. Fahr. The rate of heating is under good control and the temperatures required can be obtained conveniently. The muffle is uniformly heated, the flame passing around it, and has a door with a small opening for observation. The temperature readings are made with an optical pyrometer which is standardized in the usual way with an Amyl Acetate flame every time before making a fusing test, care being taken to have conditions as nearly alike as possible.

The coal ash which has been burned free of carbon and heated to insure oxidation of the iron, is made into a round thin cone $1\frac{1}{2}$ to 2 in. high weighing about one gram or less. This form is placed upon a thin piece of Battersea fireclay in a vertical position and set in the middle of the muffle. After heating the furnace, the blast is applied rapidly at

FIG. 9 SOFTENING RANGE OF BITUMINOUS COAL ASHES FROM FUEL USED IN TAYLOR STOKERS

first until the temperature is nearly that at which the form begins to bend. Then the heat is regulated carefully and readings made every five minutes or oftener depending upon the rate of heating; care must be taken to have the heating carried on slowly. As soon as the cone shows signs of bending the temperature is noted and the operation continued until the cone has completely bent over and touched the plate, being called the fusing temperature.

He has made a large number of fusing tests by this method, as regular routine laboratory work in connection with coal analyses, and considers the information on fusing temperature tests on coal ash of the greatest importance. While it may be true that the fusing test does not at times agree with results as obtained in practice, this may be said of any other kind of laboratory test, but when a practical test is at variance with a laboratory test the cause may usually be found and accounted for. The laboratory test gives an important clue as to the value of a coal for certain furnace conditions which cannot otherwise be readily and conveniently ascertained.

In reply is Prof. Marks' statement "relative to the separa-

¹ 50 East 41st St., New York.

tion of the more fusible constituents and thereby leaving a skeleton which fuses at a higher temperature." Mr. Palmenberg said that this difficulty does not seem to present itself when the cones are made long and thin, at least not to interfere with the tests. If the ash is thoroughly ground and mixed he believes that a complete fusion of the whole mass should take place. Furthermore, by making the ash into a long and thin form, it tends to help retain its shape during the whole time of heating and gives tests that can be duplicated to a fair degree of accuracy. The weight and height of the form does not make much difference with most coals but it is no doubt a good practice to have a standard size so that the results may be compared.

He said that whether a small amount of carbon left in the ash has any appreciable effect upon the fusing temperature will no doubt depend upon the conditions of the test and the nature of the coal ash; he had found that as much as 10 per cent carbon had no effect. If much iron is present the carbon may influence the test, but as a rule all the carbon will have burned off before fusion takes place. It is of course advisable to have no carbon present in the cone so that no reduction of the Fe_2O_3 can take place thereby raising the fusing temperature.

In regard to Mr. Hubley's statement about the relation of the fusing test to the iron oxide and sulfur, he said they seem to bear out in a general way further investigations of his that high iron and high sulfur coals give a low fusing ash, but low iron and low sulfur coals do not necessarily produce high fusing ash. The tests referred to were made on coals from Pennsylvania and as they all bear a certain relation to each other there would naturally be a corresponding relation in the fusing tests; when coal from other sources are tested the findings are very different, so that the iron or sulfur content does not always give an indication of the fusing temperature of the ash. He had recently tested the ash of a coal from Texas in which the iron oxide (Fe_2O_3) was 10.76 per cent and had a fusing temperature of only 2138 deg. Fahr.

As a further illustration to show the variable influence of iron oxide and sulfur, he presented records of tests on two lots of coal coming from Cambria county, Pa., mined from the "B" vein, the mines being about 50 miles apart. The coals in the first group represented samples taken from the face of the vein at various parts of the mine, the coals in the second group represent samples taken from deliveries. This latter coal is noted for its uniformity in quality, being prepared in a careful manner at the mine on a picking belt before being dumped into the railroad cars. In comparing the results of these two coals it is found that the first group has an ash fusing more than 100 deg. higher than that of the second group, although the Fe_2O_3 is somewhat higher and the sulfur about the same. There seems to be no strict relation of the iron and sulfur to the fusing test in either case. The results on the first group coal showed plainly the variations obtained on samples taken from the face of the vein, whereas the average samples obtained in the second group coal shipments showed few variations. The second group coal samples being obtained from a larger bulk gave a more uniform mixture of the ash constituents. These fusion tests covered a period of many months and therefore the various determinations were made under different conditions.

Mr. Palmenberg referred to a few analyses that he had

made on the ash samples before and after fusing, which indicated an increase of Fe_2O_3 in the fused cone and this he explained by the fact that these coal ashes lose some of their constituents during heating and thereby increase the ratio of the iron to the other parts. He said that the volatile constituents may be CO_2 from the carbonates and H_2O from water of combination in the silicates. The ash samples were subjected to heating in a flat silica dish with a blast flame, prior to being made into a cone for fusing, the object being to assure complete oxidation of the iron.

To show the accuracy with which fusing tests may be made, he presented records of a few duplicate determinations and Seger cone tests which he had chosen from a number of tests made in routine work. He commended Prof. Marks for the splendid and convincing manner in which he has pointed out the variable conditions met with in the work of obtaining the fusing temperature of coal ash and hoped that they may lead in the near future to the selection of a standard method for this important and valuable kind of work.

FIG. 10 EFFICIENCY VS. ASH FUSION TEMPERATURE

O. P. Hood¹ stated that laboratory methods should work towards the end that a laboratory treatment of a small sample will indicate the results that can be expected from that coal in actual practice. He said there will always be lack of agreement with commercial results until furnaces and the treatment of fires are as carefully standardized as are the laboratory methods. Calorimetric determinations have been of great value, but the potential ability of the coal thus disclosed is not made available in the furnace because of numerous unfavorable factors. He finds these factors each require careful study and may some day find their place in coal specifications. The matter of clinkering is one of the most important. If, he said, the seriousness of the clinker difficulty holds some definite relation to the fusing temperature, then a laboratory determination of fusibility becomes desirable. It can not as yet be said that such a relation is established in any large sense although the assumption seems reasonable. Some coals with a low

¹ Chief Mechanical Engineer, U. S. Bureau of Mines, Pittsburgh, Pa.

fusing temperature of the ash give no trouble with clinkering. Some coals with a high fusing temperature give trouble under certain methods of handling. He stated that there is practically no knowledge available as to the relation between laboratory results and clinker formation under furnace conditions, and that the U. S. Bureau of Mines has consistently opposed the use of fusing-temperature tests in the purchase of coal under specifications by the Government until a thorough investigation of the subject should disclose the relation between these laboratory tests and actual furnace conditions and clinker troubles.

Realizing that the results obtained for fusing temperature under different conditions of rate of heating, oxidation, and reduction would vary greatly, and that an extended investigation with a view to standardizing the laboratory test was necessary before a comparison with actual clinkering tests in commercial furnaces could be undertaken, an investigation has been conducted by A. F. Fieldner and

oxidizing atmospheres. Their investigation, which covered some fifty different coals, showed in some cases higher results in reducing atmospheres and in other cases lower results. The difference varied with the composition of the ash and the extent of reduction that took place in the test furnace. Furthermore, they do not conclude that the test should necessarily be made in an oxidizing atmosphere. Conditions in the fuel bed are variable. There are regions where ash forms in the presence of reducing agents. Incandescent carbon, CO, hydrogen and hydrocarbon gases are good reducing agents. The possibility of clinker formation under reducing conditions must therefore be considered. Keeping this in mind, the Bureau is making further investigations of the slagging of ash under the various possible fuel-bed conditions. The first step in this work is now being prepared for publication.

He further pointed out that, after a consistent laboratory method is devised whereby different laboratories can obtain

FIG. 11 APPARATUS USED IN DETERMINING THE FUSIBILITY OF COAL ASH

A. E. Hall in the Pittsburgh laboratory of the Bureau of Mines, and Professor Hood stated their conclusions from the work done before July 1, 1914, as follows:

A complex mixture of oxides and silicates like coal ash has no definite melting point. On heating a sample of coal ash it first sinters, then gradually softens into a more or less viscous slag. Hence in assigning a "fusing" or softening temperature we can only take some point or temperature range where the material reaches a certain stage of softening or degree of fluidity. The temperature at which the visible softening takes place is affected by a number of factors:

1. Oxidizing or reducing atmosphere;
2. Fineness of ash;
3. Shape of test piece;
4. Rate of heating.

The effect of these factors on the softening of ash molded into small pyramids similar to Seger cones, has been studied, and the results prepared for publication.

It is evident from the results obtained thus far that variations in the conditions under which laboratory tests are made may cause variations in the so-called fusing temperature of several hundred deg. cent., and that the fusing temperature of the ignited ash of a coal is not the only factor in the clinkering properties of the coal.

Prof. Hood pointed out that, contrary to Prof. Marks' results on the effect of oxidizing and reducing atmospheres, Fieldner and Hall do not conclude that the fusing temperature in reducing atmospheres is always higher than in

comparable results there yet remains the correlation of these results with actual experience in the furnace to determine what value fusibility tests may have in coal specifications.

E. B. RICKETTS referred to a series of tests made to determine the value of coal clinkering and ash fusion data to the power plant manager in its effect on the efficiency and capacity of the boiler plant. The tests were made in the spring of 1914 on a 650 h.p. Babcock & Wilcox boiler fired by a Taylor stoker. The boiler output was maintained at about 825 h.p. throughout the test except for one hour when the boiler was forced to between 1250 and 1700 h.p. The boiler was cleaned before each test and the conditions were maintained as nearly constant as possible throughout the series of tests. Most of these tests were of 120 hr. duration. In all thirteen coals having ash fusion temperatures varying from 2225 to 2850 deg. Fahr. were tested, the results of which are shown in Fig. 10. Mr. Ricketts pointed out that this curve is practically two discontinuous lines with a critical zone between 2375 and 2450 deg. Fahr. Lowering the fusion point from 2375 to 2225 deg., or raising it from 2450 to 2850 deg. has no effect on the efficiency, thus leaving a zone of uncertainty of about 75 deg. where the clinkering effect is doubtful. This critical zone covers the errors in testing and differences in fire conditions.

Mr. Ricketts stated that the above curve probably covers all ordinary operating conditions for Taylor stokers, but it is easily possible that the critical zone for another type

of stoker may be at a different part of the curve. In applying the results of the above tests, he has evolved the following method of determining coal values: taking any coal, the cost and analysis of which is known, as a standard, the relative value of any other coal of known composition can be determined by the following formula:

A = B.t.u. per lb. standard coal \times efficiency from curve

B = B.t.u. per lb. coal X \times efficiency from curve

C = Cost per ton of coal of transportation to bunkers and disposal of refuse for each per cent of ash in coal

D =
$$\frac{(\text{Per cent ash coal X} - \text{per cent ash standard coal}) \times C}{\text{Cost per ton of standard coal in bunkers}}$$

Value of coal X in per cent of standard coal =

$$\left(\frac{B}{A} + C \right) \times 100$$

The above method of coal valuation differs, he stated, from those heretofore proposed in that the burning qualities of the coal are given proper weight and the detrimental effect of high ash is properly discounted.

Also the method used by Mr. Ricketts for determining ash fusion temperatures differs somewhat from that described by Prof. Marks. About two pounds of coal are coked in a crucible in a gas furnace for about an hour after which the lump of coke is broken up and a stream of compressed air is fed in near the bottom of the crucible for from two to three hours until the coke is all reduced to ash. When burning the coke down, care should be taken to keep the temperature below 1500 deg. Fahr. so as to prevent premature fusion. The ash is then tested a small amount at a time with oxygen to make sure that all the carbon is consumed. It is of vital importance that no carbon be left in the ash as a small trace may cause results several hundred degrees too high. The carbon free ash is moistened with a little water and moulded in a paper cone 2½ in. long and ½ in. base. The cones are dried for five or six hours and then fused in a muffle furnace without removing the paper in which it was moulded. The cone is so placed that it overhangs the point of support about 1½ in. The point of fusion is taken when the cone reaches a 45 deg. position and is read on a Wanner optical pyrometer. (See Fig. 11.)

The question of correct melting point is in Mr. Ricketts' opinion one of minor importance so long as the results obtained are consistent. With the above described method they are able to check the same sample of coal within a few degrees and his observation of the action in the fire room of several hundred cargoes of coal from some twenty-five different sources on which ash fusion tests have been made, has consistently confirmed the results given in the test curve.

P. F. WALKER called attention to conditions under which coal may give trouble, depending very largely upon the method of handling. He referred to a situation where he had had trouble in the use of a coal with a very large amount of ash, on both hand fired grates and with stokers. He had found, however, that the firemen might be taught to handle their fires so that the difficulties are vastly different in the one case from those in the other.

ROGER DEWOLF questioned a point in the early part of Prof. Marks' paper in which a non-adhering clinker was referred to. He stated that if an ash does melt and form a non-adhering clinker, it gives very little trouble, as there is a very great difference between various coals in this regard. He asked if any work had been done that would indicate a method of determining the adherent qualities of the clinker.

THE AUTHOR said that Mr. Ricketts, in speaking of the work of the New York Edison Company, showed a curve of fusing temperatures, and their relations to clinkering troubles. My own investigations would, apparently, give just about the same results but there is this difference: I have exchanged samples of ash with the New York Edison Laboratory, and my fusing temperatures come out consistently about 200 deg. higher than those obtained at the New York Edison Company. I have calibrated my pyrometer by the melting point of nickel and by the use of the Seger cone, and I feel sure of my pyrometric work. They feel sure of their pyrometric work. Though we both come to the same conclusions, they are based on the indications of pyrometers which are strongly discordant.

F. C. HUBLEY, in speaking of this matter of discordant results between the New York Edison Laboratory and Professor Marks, said there is a rather interesting coincidence in this connection. We have Taylor stokers, forced draft, and very troublesome peak loads, a mill-load in other words, and we have specified 2700 deg. as the so-called fusing point of the ash. If you take the difference between Professor Marks' figures, I believe he stated 260 deg., and the average acceptable figure, specified by the New York Edison Company of 2450, you will obtain a figure of 2700 deg. Fahr. I have personally measured the fuel bed temperature in Taylor stokers with a radiation pyrometer, with 200 per cent radiation, and for temperature of 2700 Fahr. It would appear, therefore, as though the New York Edison Company have either misjudged the temperature of their fuel bed, or have been in error in the figures obtained in the laboratory.

SPAULDING-DRUM POWER DEVELOPMENT

BY JOHN A. BRITTON, SAN FRANCISCO, CAL.

Member of the Society

THE location of the Spaulding Dam is on the South Yuba River near Emigrant Gap. The drainage area is 120 sq. miles, and a dam 300 ft. high will ultimately be required to conserve the run-off. The water after being released from the dam will pass through six power houses; one of these, the Drum Power Station, is completed and has been in operation for nearly a year, and four have their foundations laid. A total head of over 4000 ft. will be utilized. After passing through the sixth power house, the water is to enter the irrigation system by means of which it will be possible to irrigate over 60,000 acres of land.

a As results were required from the development by the end of 1913, it was necessary to select such a method of construction as would ensure completion by that time, and reject anything that would not meet that condition.

It was at first proposed to build the dam from concrete made of crushed granite and a sand and gravel found near the dam. This local gravel would not stand the test of crushing strength, namely over 1000 lb. per sq. in. at ninety days, and therefore had to be rejected. Finally, a gravel deposit was selected on the Bear River near Colfax. This material was very well graded, clean, made excellent concrete and was

FIG. 1. GENERAL VIEW OF THE SOUTH YUBA RIVER GORGE, BELOW SITE OF THE SPAULDING DAM

The foundation of the Spaulding Dam was placed in November and December 1912, and the dam was "poured" between May and December 1913, so that the 150,000 cu. yd. in the dam was placed in less than nine months. The reservoir was filled on February 1, 1914, to an elevation of 225 ft. and Drum Plant was put in operation on November 26, 1913. The entire work was carried through ahead of schedule and estimates of costs were realized.

Features of the Spaulding Dam which will interest engineers and construction men are:

- a The method of construction, especially with reference to obtaining speed of construction
- b The variable radius arch design
- c The expansion joints
- d The drainage system
- e The water control or discharge system

Abstract of paper presented at the San Francisco local meeting of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS, on September 10, 1914.

located in such position that the desired speed of supply could be obtained. The material was loaded by steam shovel into 30 cu. yd. gondola cars and hauled to Colfax over the track of the Nevada County Narrow Gauge Railroad. The cars were dumped into large bunkers at an elevation of about 375 ft. above the bottom of the dam.

From the storage bunkers the gravel was conveyed by belt conveyors to service bins located over four one-yard Smith mixers. From thence, the concrete was carried by chutes to towers located over the dam and from these towers it was distributed by chutes to the part of the dam desired. For the lower part of the dam, the concrete was dropped through a series of baffles to the elevation desired, from whence it was carried by chutes to its destination. In falling through this set of baffles the mixing was materially aided. At the end where the concrete towers were located, after the dam had reached the grade of the chute from the mixing plant, the concrete was elevated by belt conveyors and distributed from other towers and chutes. The concrete was allowed,

as far as possible, to flow onto the dam by its own weight—like a lava flow—and only five men were required to distribute 1000 to 2000 yd. per day. The grade of the chutes was 5 in. per ft. and of the belt conveyors 18 deg. and 20 deg. The speed of the belt was about 420 ft. per minute and a 28 in. belt was used.

This is, I believe, the first concrete that has been successfully transported by belt conveyors. Successful transportation depends on a wide belt, well-troughed, and on keeping the belt clean. To clean the belt a rotating brush, a stream of water and a compressed air jet were used. A thousand yards of concrete per day were easily handled over a single belt, and tests showed as high as 200 yd. per hr.

The gravel mixture was tested hourly at the gravel pit and samples were again taken on the belt conveyors at the mixing plant. Any deficiency was made up by crushed rock, or sand as required. Three samples of the concrete were taken off the dam daily and these were tested at 7, 28, and 90

more work for the instrument men in locating the lines. The increasing radius, as the canyon width increases, gives a natural batter to the front face, and the entire appearance of the dam is one of strength.

c Concrete will contract in setting and form cracks. In order to control the position of the cracks to prevent them from weakening the dam, radial contraction joints were located every 80 ft. along the length of the dam. The dam was therefore really built up of 80 ft. keystone concrete blocks, and the writer considers it advisable to use contraction joints in all high or long dams. These contraction joints may increase the initial leakage, but after the reservoir has been drawn down somewhat following the first filling and when the dam is at a low temperature, grout may be forced into all joints and leakage cut off.

d Although a drainage system is advisable in a gravity dam to prevent uplift due to hydrostatic pressure, it is not so necessary in the arched type of dam. One was provided,

FIG. 2 PROFILE SHOWING LOCATIONS OF THE VARIOUS DEVELOPMENTS ON THE SOUTH YUBA AND BEAR RIVERS

days, six months and a year. The location where sample was taken was marked on each, so that records of the strength of the dam at all points and of the increase of strength with age are available.

b The dam site immediately suggested an arched dam, as the walls of the canyon are solid granite and converge downstream. The scientific design of any structure demands that factors of safety throughout shall be consistent in order that a structure of uniform strength may result; and, since in building an arched dam across a river canyon, we are really building sections of a pipe spanning the canyon, in order to build a dam of uniform factor of safety from top to bottom, the thickness of the dam must vary with the width of canyon and with the head of water. These considerations lead to a design having a variable radius, increasing as the canyon becomes wider. This results in a structure having uniform elasticity, as far as possible, all parts of the concrete being strained practically to the same amount. The design is calculated for a strain of 24 tons per sq. ft., assuming all the strain to be taken up by arch action. Ultimately, the dam will be carried up to an elevation of about 300 ft.

The arch type of dam requires no more labor in building forms than does the single radius arch, although it involves

however, in the Spaulding Dam, consisting of two parallel rows of holes running vertically from top to bottom of the dam and to bed rock.

A drainage tunnel was built in the dam following generally parallel to bed-rock, and a discharge tunnel connects with this tunnel to the rear of the dam. The main discharge tunnel from the reservoir is about 70 ft. elevation above the bottom. At an elevation of 100 ft. above this, a second outlet tunnel was built connecting with the first tunnel through an incline rise and giving in effect a gate tower with two openings. Near the upper end of these tunnels were placed 6 ft. steel butterfly valves, connected with the main tunnel by appropriate steel tapers.

At a distance of 694 ft. from the point of convergence of the upper tunnel rise and the original tunnel, a concrete bulkhead was placed, and a new tunnel was driven outward. The whole of this main tunnel to the gates was concrete lined and the last 120 ft. was reinforced sufficient to carry the total pressure that would exist with the reservoir level at 300 ft. in the ultimate dam.

After rising 13 ft. the lined tunnel enters a steel taper, which emerges into the operating chamber and ends in a cast steel manifold, to which are attached two 36 in. Allis-Chalmers pressure regulating valves on the side and a 72 in.

FIG. 3 DOWNSTREAM FACE OF SPAULDING DAM, SHOWING STEPS AND BOND RAILS PROVIDED FOR RAISING DAM TO 300 FT.

FIG. 4 VIEW OF SPAULDING DAM COMPLETED TO HEIGHT OF 225 FT., SHOWING ARCH, SPILLWAY AND CONCRETE PLANT

butterfly valve on the end. A variable head two runner turbine will later be extended beyond this butterfly valve, but at present the valve dead-ends this taper pipe while the water is drawn off by hydraulically-operated pressure regulators which each have a 36 in. clear opening, guarded by a 48 in. butterfly valve for emergency and repair purposes.

The valve closing the 36 in. port opening is a "mushroom" shaped or conical disc valve, rising up into the stream and being operated by a shaft connected to a disc of slightly larger area in a chamber above to which pressure is applied or withdrawn as needed. By turning handwheel on a screw thread of the shaft extended up through a stuffing box, the

1000, finally coming to the end of a spur 1375 ft. above the Bear River, where the forebay is perched.

The length of canal is 39,631 ft., having five sections (in all 2602 lineal ft.) of box flume built at sharp ravines encountered in the length of canal. The canal averages 11 ft. in the bottom width, and 7 ft. in depth, with side slopes of $\frac{1}{2}$ to 1 and 1 to 1, depending upon the formation. The ultimate capacity will be 350 cu. ft. per sec, with an average of 7 ft. depth of water. The canal is broken in two places where siphons are used. The first siphon is a combination of 96 in. wood stave and 84 in. steel tube passing around the Tahoe Forest Reserve, and having a length of 1868 ft., with a maxi-

FIG. 5 DETAILS OF THE DRUM POWER HOUSE, SHOWING ARRANGEMENT OF EQUIPMENT

attendant can lock the gate at any position according to the flow required.

The valves discharge into steel draft tubes, imbedded in concrete, which turn the water out horizontally into a surge pit below the level of the main tunnel. They are now operating under a static head of 140 ft., and the hollow cone of water shooting out through the gate opening has a velocity of 93 ft. per sec., with no valve vibration.

It is proposed to install later at this place a turbine and generator, consuming about 5000 kw. from the static energy of the impounded waters as they are drawn into the Drum aqueduct, so that the turbine will become the control gate and the power now lost will be sent to the transmission system.

From the Spaulding tunnel, the water is carried 8.5 miles to Drum forebay by $7\frac{1}{2}$ miles of earth canal, 2002 ft. of flumes, and 3600 ft. of siphons. The canal system begins at a small elevation above the South Fork of the Yuba River and follows the mountain side, swinging into the head waters of the Bear River and thence along a light grade of 1 ft. per

1000, finally coming to the end of a spur 1375 ft. above the Bear River, where the forebay is perched.

The length of canal is 39,631 ft., having five sections (in all 2602 lineal ft.) of box flume built at sharp ravines encountered in the length of canal. The canal averages 11 ft. in the bottom width, and 7 ft. in depth, with side slopes of $\frac{1}{2}$ to 1 and 1 to 1, depending upon the formation. The ultimate capacity will be 350 cu. ft. per sec, with an average of 7 ft. depth of water. The canal is broken in two places where siphons are used. The first siphon is a combination of 96 in. wood stave and 84 in. steel tube passing around the Tahoe Forest Reserve, and having a length of 1868 ft., with a maxi-

imum head of 237 ft. The second or Drum siphon crosses a draw just before reaching the forebay; it has a length of 1888 ft., is 102 in. in diameter, and has a maximum head of 128 ft. Altogether, the canal required 8511 lineal ft. of masonry rock wall and 16,313 lineal ft. of dry rubble wall.

The Drum forebay is a large regulating reservoir, gouged out of the top of a hill having an area of 20 acres. It is perched 1375 ft. above the Drum power house and is a lake of 444 acre ft. capacity with a depth of 34 ft. of water.

The forebay dam was constructed entirely of earth and clay taken from within the bounds of the dam. The excavated materials were handled direct by wheel- and fresno-scrapers or were plowed and loaded through traps, or directly by steam shovels into wagons and hauled to the site on the dam. The materials were well worked together by harrowing, rolling and wetting after being freed of all rocks. The latter were used in the 30 ft. rip-rap facing of the inner slope.

After the completion of the forebay dam, which is 230 ft. wide at the base and 54 ft. high at its maximum section, and

contains 266,219 cu. yd. of materials, the bottom and sides were puddled with a good quality of clay found within the enclosure.

The spillway is just back in the canal from the forebay. It is 75 ft. in width. A maximum depth of 1.75 ft. overflow would be required to care for 400 sec. ft.

The waters of the forebay are brought to the power station through a steel pipe 72 in. in diameter which will ultimately be duplicated. This line is 72 by $1\frac{1}{4}$ in. riveted steel at the intake, diminishing to 52 by $1\frac{1}{4}$ in. at the power house where the static head of water is 1375 ft. The length of this penstock is 6282.2 ft., having a net weight of 2,920,000 lb.

The penstocks terminate in cast steel Y-pieces, each branch being again divided by secondary Y-pieces. The piping is so arranged that three units may be fed from either penstock. The usual method of operation will be with each penstock supplying two main units.

The main gate valves are of cast steel construction, with single parallel faced discs arranged to withstand pressure from either direction. They have 36 in. openings and are operated by reversible impulse water motors. The special fittings are all of cast steel, while the straight connecting pipes are of riveted steel. The connecting pipes were fitted in place after the Y-pieces and nozzle bodies had been set, and thus perfect alignment of all parts was secured without forcing any part into place with the attendant possibility of setting up stresses in the parts other than those caused by the water pressure.

At Drum power station, on the south bank of the Bear River, a site for a power house was secured by sluicing 40,000 cu. yd. of hill slope and finally blasting into bed rock for a site 100 ft. by 500 ft. long.

The erection of a reinforced concrete and steel building to house four 12,500 kw. generators was completed in November 1913. The initial installation of two 12,500 kw. generators was made and the same were "thrown" into service November 26, 1913.

The main water wheels are of the single jet impulse type and each develops a maximum of 10,000 h.p. at normal speed of 360 r.p.m. It would be difficult to obtain a greater output at this speed and head with high efficiency. The wheel centers are of the double disc type and the buckets are bolted to the discs with the "chain" arrangement.

The governors, which are of the oil pressure type, actuate the deflecting nozzles. The governing is simple and may be operated at any desired speed with perfect safety. The size of the jets is controlled by needle valves which are operated by motors controlled from the switchboard. With a little attention on the operator's part, this combination permits very good economy in the use of water and very good governing with a high degree of safety and simplicity.

Special attention was given to securing a low temperature rise of the main generators, and to devising a rotor construction which would withstand the high stresses set up under runaway conditions. Exceptionally good ventilation is secured by enclosing the generators and bringing all the air into the machine from outside the building. A rotor of great strength is obtained by building up the hub of the rotor of steel discs. Pressing these hubs on to the shafts was avoided by placing the entire hub in a tank of water which was brought up to the boiling point and held there until the rotor was thoroughly heated. This treatment expanded the

bore of the rotor by about 20 thousandths of an in. The shaft, which was 8 thousandths larger than the bore of the rotor at normal temperature was simply lowered into the rotor, there being about 12 thousandths to spare. The water wheels were placed on the shaft by the same process. The assembled revolving parts weigh about 83 tons. The fly-wheel effect of these parts is over 1,750,000 lb.-ft. squared, and the energy stored in them when running at normal speed is over 38,500,000 ft.-lb.

A double circuit 110,000 volt transmission line is provided on steel towers, of which there are 730 in all in place. The initial single circuit extends 110 miles westerly from Drum power house to Cordelia sub-station, which is the load center of Pacific Service. From this point, the power is distributed radially at 60,000 volts to the cities and valleys

FIG. 6 INTERIOR VIEW IN THE DRUM PLANT

surrounding the bay. The standard spacing of towers is 800 ft. centers, with 30 ft. minimum ground clearance, requiring a height of tower of 78 ft. to top cross arm and 82 ft. over all. These towers themselves are of three weights, for straight line work, for spans up to 1500 ft. or angles up to 15 deg., and for use on dead ends and angles over 15 deg. The maximum size of conductor for which they are designed is 4/0 copper. At the present time, the one circuit is made up of 51 miles of 3 0 seven strand copper and 59 miles of 266,800 c/m 19 strand aluminum cable. The longest span is 4056 ft. at Greenhorn Gulch above Colfax.

The Cordelia sub-station located at the end of the Drum-Cordelia 110,000 volt transmission line was constructed in 1913 for the distribution of the 60,000 volt circuits of the Pacific Service.

DISCUSSION

E. H. VARNEY asked what velocity the water wheels developed in case they lost the load.

J. P. JOLLYMAN¹ said that the speed of these generators is 360 r.p.m. The velocity of that point on the bucket upon which

¹Electrical Engineer Pacific Gas & Electric Co., San Francisco, Cal.

the center of the jet impinges is about 46 per cent of the velocity of the jet itself; and in the event of the loss of load other than friction (when of course the wheel will speed up) the speed will reach approximately 100 per cent over normal speed. That is about the limit of the overspeed that can be reached. It is probable that on a unit of this kind 90 per cent of overspeed would be the limit. As the speed goes up, there is a certain amount of interference between the buckets and the jets themselves. However, it was considered in the Drum plant that 100 per cent overspeed might possibly be reached, and the generator was designed so it might operate at this speed without any stresses exceeding the elastic limits, so that in the event of a runaway, no part would be deformed—an important consideration.

The generators were tested in the factory to double speed.

sary therefore to have the rotors pressed on just as tightly as it is practical to handle them. The factory estimated that 750 to 1000 tons pressure would be required to force the rotor on the shaft, the fit being made in four steps of different diameters. In other words, of the total of about 44 in., the press would have to force the rotor ahead about a quarter of that distance. We thought it more expedient to heat the rotor and shrink it on, as this would avoid any damage to the shaft itself and any possibility of getting the rotor stuck, besides obviating the necessity for a press to give a thousand tons pressure.

The units in one of the Big Creek stations of the Pacific Light & Power Company are very similar to these units, in fact, they are almost identical, and I understand that in pressing the hubs in some of their shafts, this company had

FIG. 7 CONSTRUCTION VIEW OF THE 96-INCH WOOD STAVE PIPE ON THE TAROE SIPHON

That is something that is not always done, although the requirement is one that should be made and met to insure safe operation under all conditions. In some places, in order to take every precaution, this double speed test is made in a deep pit, and the machines are usually operated on a vertical shaft, and if they go to pieces they simply damage the sides of the pit. In the case of our machine, the builders (the Westinghouse Electric and Manufacturing Company) were so sure of their designs and workmanship that they tested the machine at double speed in a horizontal position above the floor.

When the machine is operated at excess speeds, the centrifugal forces become very high because at normal speed the peripheral velocity of the rotor is high, being in our case about 12,000 ft. per min. The centrifugal stresses are so high that it is difficult to maintain the rotor tight on the shaft, and cases have been known where rotors have loosened on the shaft at runaway speed. The hub of the rotor was bored .008 in. smaller than the shaft. Any less allowance might permit the rotor to loosen at double speed, and it is neces-

some little difficulty in handling the work. They had a very elaborate press, and took quite a long time to perform this work. As I remember, the third day from the time we started, the rotor was on the shaft. The entire water wheel with the buckets on was also heated in the same manner. These wheels could undoubtedly have been pressed on with a very moderate pressure, say, 200 tons, as the fit allowance was much smaller than the hub of the rotor.

The rotor is practically solid, and the object of this is twofold, to get the maximum strength, and to obtain the maximum amount of fly-wheel effect consistent with the amount of space occupied. In other words, we consider it a great advantage to get as much fly-wheel effect as possible without actually increasing the size of the machine. The fly-wheel effect of the rotor is about 1,750,000 sq. ft. and the stored energy is about 33,000,000 ft.-lb. or 1000 h.p. for a minute, and to bring the rotor from rest to full speed or stop it from full speed would require the application of 1000 h.p. for one minute. That is a considerable amount of stored energy.

In governing this plant, we are able to hold the speed within one-quarter cycle of the speed we term normal, and that is very close governing we think for so large a system. We have many fluctuating loads, although the fluctuations in the total load balance up to a remarkable extent; three or three and a half or four per cent is the maximum variation that we receive on the system as a whole. That may be 100 per cent on the governing machine or on the particular unit that is governing; but on the system as a whole three or four per cent from one minute to the other will cover the variations in load. The minimum load is roughly 40,000 kw., and the maximum load is 110,000, and this year it will probably

J. P. JOLLYMAN said that the essential requirements in the design of a bucket on an impulse wheel are that the water be turned and discharged at as low a velocity as possible so as to absorb the maximum energy, and that the bucket enter and leave the stream in somewhat the same manner that the teeth on a gear enter and leave those on a rack. As a tooth on a gear wheel rolls into one on a rack, the back of it must not interfere with the next tooth on the rack, and that principle must be observed in water-wheel practice. In other words, as the bucket gets into the moving stream the back of the bucket must not touch the water that is cut off by the face.

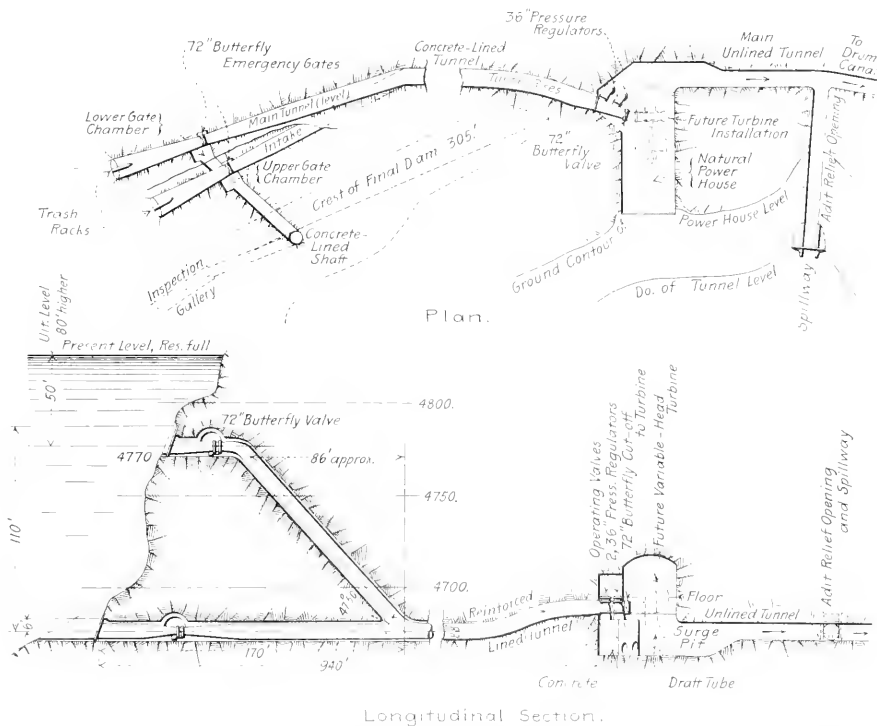

FIG. 8. DETAILS OF THE UPPER AND LOWER INTAKES AT THE SPAULDING DAM, SHOWING GATE CHAMBER

reach 125,000. The variation from one hour to another is taken up by properly adjusting the loads on different units, but only one unit in one water wheel plant actually governs.

THOMAS MORRIN said that some three or four years ago several engineers called on W. R. Eckart, Sr., who had then practically finished the development of the face of the bucket and had turned his attention to the back. Mr. Eckart had found from a demonstrating apparatus that the bucket in use up to that time carried what we call in steamboat parlance, "dead water" on account of the form of the back of the bucket which offered a material resistance.

The principle of back design has been very much emphasized in the past few years. Mr. Eckart was one of the first to develop the idea and there are also others who have worked along these lines.

There are other requirements which of course must be met. The bucket must catch all of the water on the wheel. This limits the minimum number of buckets to probably 15. The Drum wheel has 17 buckets. If you have less than 15 buckets, all the water will not be caught.

The attaching of the buckets to the disc is also an item of very considerable importance, in view of the manner in which the stresses on the attachment vary. If the bucket is running free from the jet, it is acted upon by centrifugal forces only, which tend to throw it off the wheel. When

struck by the jet, the bucket is acted upon by a combination of tangential and centrifugal stresses, which may cause a reversal of stress on some of the attaching bolts. The reversing stress is naturally very hard to take care of, being a hammering effect first in one direction and then in the other. Reversing stress has caused a good deal of trouble in some of the wheels where the design of the attachment has not been properly worked out.

F. H. VARNEY said that he understood that at different times more or less trouble was experienced in plants such as described from erosion and sand-blast action and so forth. He asked Mr. Jollyman what had been done in the Drum to overcome that action, and also what classes of metal are now used for the water wheels, what metal the buckets and discs are made of and what metal the buckets are held on with.

J. P. JOLLYMAN answered that in some of the older designs of water wheels, corrosion which has the appearance of sand-blast action or pitting has taken place usually at the bottom of the lip of the bucket where it first cuts into the jet, and the buckets have been honeycombed and eaten away. It was thought for a considerable time that this was due to sand in the water; but the same action took place in some cases where there was no sand. Where the water came from settling reservoirs and was positively clear, the same erosion was found in some cases. Then it was thought that possibly air in the water, being liberated at this point, was causing the erosion. The principal cause was finally decided to be improper design. If there is interference between the back of the bucket and the jet, in other words, if the back of the bucket presses against the jet instead of keeping away from it or if in the course of the bucket's path through the jet, pressure is put on a point and then released suddenly, pitting will take place. I believe that most engineers now concede that pitting can be very largely avoided by so designing the parts, that the water will be deflected uniformly, and no very sudden change in the direction or rate of motion of the water allowed to take place and that there should not be any interference between the back of the bucket and the jet. With those precautions observed, there seems to be very little honeycombing, pitting or wearing.

A certain amount of wear on the face of the bucket is unavoidable, but with buckets of good design this wear is very small. We have had wheels at DeSabra operating under 1531 ft. head (that at Drum is 1375 ft.) for eleven years and they do not show very much wear. The original buckets are still on the wheels and have been used almost constantly. Those buckets and the buckets on the Drum wheel are cast steel. At one time it was thought that buckets of bronze would wear better than buckets of cast steel, but I do not believe that the material is as important as the design. The pitting is more easily and more correctly explained by incorrect design than by chemical action or the material. In places where a large amount of sand is carried by the water, I think it is probable that bronze has a slight advantage over cast steel. The bronze seems to have something of the effect of rubber which is very slightly eaten away by sand-blast as compared with a piece of steel. Bronze seems to have a certain yield or tendency to hold together that cast steel does not have.

F. H. VARNEY asked whether vanadium steel had been used.

J. P. JOLLYMAN said that he did not believe so. He thinks the buckets are cast from open hearth steel. The wheel centers on the Drum machines are cast steel. They had some wheel centers made of steel similar to that used in armor plate; but they believe now, with the increased knowledge of what may be done in the way of attachment, that it is not necessary to have a steel harder than nickel steel or good open hearth steel for these conditions. For very much higher heads than occur in present practice other steel may be necessary.

WM. J. DAVIS, JR., asked how the speed regulation governors of the Drum Power House are set.

J. P. JOLLYMAN answered that the drop in speed from no load to full load on the governors is adjustable. With one unit governing the system they adjust that for zero drop in speed. In other words, the unit tends to maintain a uniform speed at any load. Of course if more than one unit is required to govern, then both must be given a small drop in speed, about one or two per cent, in order to let them operate in parallel and both govern. As a matter of fact the Drum units are of sufficient capacity to govern alone; and with one unit governing we set the governor so it gives the same speed at full load as it does at normal. The whole system is then governed.

WM. J. DAVIS, JR., asked what is the effect of the setting of the governors on the parallel operation of the Drum Power House with the steam plant in San Francisco. He thought it would be desirable to have the steam plant take the fluctuations of load, and the water plant a constant load.

J. P. JOLLYMAN said that would be the best arrangement for operation. The fact is that the transformer capacity between the hydro-electric system and the steam plant is limited and it is hardly possible to let the steam govern the whole system for fear of overloading the transformers. The San Francisco steam plant has a capacity of 40,000 kw. The transformer capacity between the hydro-electric and the steam is only 9000 kw. They do not attempt to carry the whole of the San Francisco load from transmitted power. In fact their system at the present time of the year could not do that. It is rather the better condition to govern by steam and use all the water. As a matter of fact, to do that would throw fluctuations into this plant of greater amount than its present capacity. With a zero drop in speed for changing load, the Drum governing machine tends to take all the fluctuations out of the system; and the operators of the steam station have to watch the loads on the connecting cables very closely to assist in the governing, to prevent the overloading of these cables.

The parallel operation of the system as a whole is very satisfactory indeed, there being no reciprocating units used but only rotating machines. The steam turbines and the water wheels are all of uniform rotating speed. There is no surging between one unit and another and no tendency to drop out of step.

RECENT DEVELOPMENTS IN STEAM-ELECTRIC GENERATING STATIONS

BY JOHN HUNTER, ST. LOUIS, MO.

Member of the Society

THE meeting of the St. Louis Local Section on October 28, 1911 was a joint meeting of the Associated Engineering Societies of St. Louis, held under the auspices of the St. Louis Section of the Am. Soc. M.E. at which an address was delivered by John Hunter, chief engineer of power plants of the Union Electric Light and Power Company of St. Louis, Mo. Mr. Hunter summarized the equipment of the large generating stations in New York, Boston, Philadelphia, Washington, Detroit, Chicago, Milwaukee and St. Louis, and traced in an interesting manner the phenomenal development in power generation as exemplified in these plants. Some extracts from the address are given herewith, as abstracted from a report of the meeting that appeared in Power, December 22, 1914.

At present there are 15 different public-service corporations supplying power to the five boroughs of the city of New York. The New York Edison Co., operating the great Waterside stations, dates back almost to the beginning of the electric-light industry. The old Pearl Street Station, the first Edison electric-lighting station in New York, was built in 1882. Up to the advent of high voltage, alternating-current transmission and distribution, there were numerous steam stations of the non-condensing type for direct-current generation built here and there about Manhattan Island. The first plant of any considerable size was Waterside station No. 1, built in 1900 and designed for sixteen 3500-kw. alternating-current generators driven by vertical compound engines. In 1905, after eleven of these units had been put in, the equipment was completed by the addition of three 5000-kw. vertical turbines and two 10,000-kw. horizontal turbines. In 1911 and 1912 four of the engine units were removed and three 20,000-kw. vertical General Electric turbine units installed. At the same time one of the 5000-kw. turbines was reworked for 9000 kw. The total capacity of the plant is thus 123,500 kw.

This station was rapidly outgrown and Waterside station No. 2 was built in 1909. It adjoins the No. 1 station and together, so far as operation is concerned, they are practically a single station and form the largest steam plant in the world, having a combined capacity of about 215,000 kw. The No. 2 boiler house contains ninety-six 650-hp. Babcock & Wilcox boilers operating at 200 lb. pressure with 125 deg. superheat. The boilers are in eight rows across the boiler house, six in a row and on two decks.

In the turbine room there are six 8000-kw. Curtis turbines, two 8000-kw. Westinghouse turbines and two 14,000-kw. Curtis turbines. Each of the Westinghouse turbines drives a twin generator, one 25-cycle, 6600-volt, and the other 60-cycle, 7500-volt. Either is used as required; they run at 750 r.p.m. The main generating units are equipped with surface condensers, utilizing salt water from the East River for cooling. To provide against a shortage of coal in case of

strike or delayed deliveries, the company has a storage yard at Shadyside, on the New Jersey shore, capable of stocking 200,000 tons.

The Fifty-ninth Street station of the Interborough Rapid Transit Co., which carries the subway load, is of special interest in that it has five of the largest exhaust-steam turbines in existence. The original installation was completed about 1903 and contained nine 700-kw. Allis-Chalmers (combined double horizontal and vertical, 11,000-volt, 25-cycle). Later, about 1905, three 1725-kw. Westinghouse turbines were installed. Each of these engines had two horizontal high pressure cylinders 44 in. diameter and two vertical low pressure cylinders 88 in. diameter, with a common stroke of 60 in. The original boiler installation was fifty-two 600-hp. Babcock & Wilcox water-tube boilers, with space for 20 additional boilers; eight more were eventually put in.

Due to the rapid increase in the demand for electric current from this company, the capacity of the station had to be increased. Five low-pressure Curtis turbines of 7500-kw. capacity were installed between and to one side of the reciprocating engines without purchasing additional real estate. The method used in starting up the combined engine generator and low-pressure turbine is simple. Excitation is applied before starting, then, when brought up to speed, the machine is synchronized in the usual manner. While starting in this way, the induction generator connected to the low-pressure turbine acts as a motor until sufficient steam passes through the engine to carry the turbine above synchronous speed, when it immediately becomes a generator and picks up the load. The leads of the turbine are tied in solidly to the main generator leads through knife switches which are never opened.

The net results obtained by the installation of the low-pressure turbines in this station have been summarized as follows:

- An increase of 100 per cent in the maximum rating of the plant.
- An increase of 146 per cent in the economic output of the plant.
- A saving of approximately 85 per cent of the condensed steam for return to the boiler.
- An average improvement in economy of 13 per cent over the best high-pressure turbine results.
- An average improvement in economy of 25 per cent (between the limits of 7000 kw. and 15,000 kw.) over the results obtained by the engine units alone.
- An average unit thermal efficiency between the limits of 6500 and 15,000 kw. of 20.6 per cent.

In the Seventy-fourth Street station of the Interborough Rapid Transit Company, there are 64 Babcock & Wilcox boilers and the generating equipment comprises eight Allis-Chalmers 7500-kw. combined horizontal and vertical Corliss engines, similar in all respects to the original installation in the Fifty-ninth Street station, and one 7500-kw. Westinghouse horizontal turbine of the same rating as the engines.

Abstract of paper presented at the St. Louis local meeting of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS, on October 28, 1914

The growth of this company's business again required additional capacity from its generating stations and it has now decided to remove four of the engine units and install three Westinghouse turbines, each of 30,000-kw. capacity. These turbines are cross-compound units. The high pressure element is a single-flow turbine operating between steam-boiler and approximately atmospheric pressure. On leaving the high-pressure cylinder, the steam goes through a receiver separator and then into the double-flow, low-pressure cylinder. The high-pressure end operates at 1500 r.p.m. and the low-pressure expansion end at 750 r.p.m.; both ends are controlled by a single governor driven from the high-pressure spindle. The two generators are electrically tied together, therefore no governor is needed on the low-pressure end. The guaranteed water rate is 11.27 lb. per kw.-hr. Steam enters the center of the turbine through two openings and then divides, one half going each way to a condenser at each end.

The Philadelphia Electric Co. has two main generating plants, stations A-1 and A-2. Station A-1 is equipped with turbines varying in size from 750 kw. to 15,000 kw. For this station a 35,000-kw. General Electric turbine is now being built. While it is 5000 kw. larger in capacity than the large Westinghouse cross-compound turbine, it is contained in one unit and involves special characteristics recently developed by the General Electric Co. To permit of greater mechanical stability and to provide greater area in the low-pressure end, the casing is divided into two parts with a bearing between. The revolving field is an enormous steel forging, with milled slots, similar to small machines. The armature frame is cast in two halves, each of which represents about the limit of casting and transportation possibilities. The turbine and generator are mounted on a common base, thus constituting a single generating unit, in this respect surpassing anything else heretofore attempted.

Delray plants Nos. 1 and 2 of the Detroit Edison Co. are four miles southwest of the business center of Detroit, on the banks of the Detroit River. No. 1 station, built in 1904 and containing four 3000 kw. units, now has four 8000-kw. Curtis turbines. No. 2 station, built in 1908, has three 14,000-kw. and one 15,000-kw. turbines, making the turbine rating of the two plants 89,000 kw.

The original design of the No. 1 plant included a surplus of boiler capacity for the purpose of permitting the four original 3000-kw. Curtis turbine sets to operate noncondensing; the exhaust steam was to be supplied to salt refiners in the vicinity for evaporating brine. Twenty-four 500-hp. Stirling water-tube boilers were installed, set in four batteries of six each. Each boiler contains 4834 sq. ft. of heating surface. The second bank of tubes forms the superheater with an area of 1500 sq. ft. and superheating to 600 deg. Fahr., or 200 deg. Fahr. above the normal temperature of the steam at 210 lb. per sq. in.

The first four turbines in station No. 1 were run condensing. The plan for supplying exhaust steam to the salt refiners was never carried out because the company's load had so increased that it was found necessary to install an additional 3000-kw. unit; this was done without increasing the boiler equipment. The first four 3000-kw. machines of 1904 were replaced in 1911 by 8000-kw. units of similar type, equipped with Worthington 16,000-sq. ft. surface condensers of the base type.

The No. 2 turbine room has three 14,000-kw. and one 15,000-kw. vertical Curtis General Electric turbine units,

which, like the machines in No. 1 turbine room, furnish 4600-volt, 60-cycle, three-phase energy. The turbines are ventilated by forced draft and the dampers are so arranged that air can be taken from the engine room and delivered to the outside, or, as is desirable in winter, the outside air can be taken into the machines and delivered to the engine room.

Of special interest in connection with the Delray plants are nine big double-fired Stirling boilers in the No. 2 power house, each having a rated capacity of 2365 hp. The normal output is 7000 kw. in regular service and they have been drawn upon for 11,000 kw. during short periods. All are equipped with Taylor stokers, which have a nominal area of 300 sq. ft., with a heating-grate ratio of 79 to 1. The steam pressure carried in this plant is 205 lb., with a 150 deg. superheat. This is one of the first stations to develop high superheat. The original steam fittings were cast iron and had to be changed to steel after five years, weakness in the iron having developed. The superheaters are mounted between the boiler tubes proper.

Each of the 54-in. steam drums has eight 4½-in. safety valves besides four 3-in. valves on the superheaters. The advantages in the use of these large units are found in a decreased cost per horse power of rating; a lower radiation loss per unit of capacity, hence a higher efficiency, and they occupy smaller area per unit of output. Repairs on these large units are not excessive and do not exceed the usual cost per horse power with small-size units. The combined boiler and furnace efficiencies obtained run from 80 per cent at 75 per cent rating to 76 per cent at 200 per cent.

With the city's phenomenal growth in demand for electric energy, the Detroit Company has under construction a 100,000-kw. plant at Connor's Creek, which is at the opposite end of the city near Lake St. Clair. This plant is expected to be completed to take the full load of 1915.

By far the greater part of the electrical energy generated by the Commonwealth Edison Co. in Chicago, is produced at the Fisk Street and Quarry Street stations, which are on the south branch of the Chicago River. The engine room of the Fisk Street plant is 630 ft. long and was originally designed for fourteen 5000-kw. vertical Curtis turbine units. The first unit was installed in 1903, but later it was decided to use 12,000-kw. units instead of 5000. One of the 12,000-kw. units had been installed when the advance in the art led the company officials to decide that the last four units should be of 20,000-kw. capacity, or larger, and of a horizontal type. Of these two are already installed, one a General Electric 20,000-kw. and the other a Parsons 25,000-kw. turbine.

The boiler house of the Fisk Street station was originally designed for fourteen batteries of eight 500-hp. boilers, and ten of these batteries, comprising eighty boilers, are already in use. The remainder of the boiler house will be filled with four batteries, each of four boilers and each boiler having 12,250 sq. ft. of heating surface, with an equipment of economizers and induced draft fans with which, it is anticipated, the boilers can be worked at 200 per cent of rating. The combined generating capacity of all the units at Fisk Street is 165,000 kw. When running at full capacity the station will consume nearly 2000 tons of coal a day, and nearly 200 tons during the maximum or peak hour. The number of heat units required to generate a kilowatt-hour with the old equipment was approximately 28,000; with the new equipment it is something less than 20,000. This would be 2 lb. of coal at 10,000 B.t.u. or 1.43 lb. at 14,000 B.t.u.

The great increase in the business of the Commonwealth

Edison Co. made it necessary to build the Quarry Street station in 1908. The two stations are operated together as one electrical generating station, being connected by tie lines in two tunnels.

Arranged in two rows parallel to the turbine room are eight 500-hp. water-tube boilers for each generating unit, or 48 for the entire station. The original boiler setting at Quarry Street was a departure in furnace design in that the furnaces were placed under what is usually considered the rear header. In other words, the slope of the tubes was up and away from the furnace rather than the reverse. The advantage sought was in the long combustion chamber, expanding in volume, which made for more complete combustion of the fuel and an increase in boiler efficiency. These boilers were equipped with horizontal passes. After a time it was found that the maintenance costs were running high, and it was decided to equip the last six of the boilers with standard settings, although at the same height as the other; this gave a larger combustion chamber than is the usual practice. Eight boilers are independently connected to each of the six turbines, although cross connections are available in case of emergency. Quarry Street was the first station in the United States to install centrifugal boiler feed pumps.

The rate at which the business of the Commonwealth Edison Co. was increasing made it evident in 1910 that the Fisk and Quarry Street stations would be inadequate for the service and plans were immediately made for additional station equipment. The new Northwest Station has been the result. Between 1908 and 1910 the maximum load of the system grew from 117,370 kw. to 182,600 kw., an increase of 55½ per cent. In 1912 the maximum load had further increased to 200,000 kw. In planning for the capacity of the new station the indications were that for a number of years the increase would average at the rate of 15 per cent per year. This rate of increase, applied to the load of 200,000 kw. in 1912, indicated that the net increase of load during the following five-year period would amount of 220,000 kw.

Accordingly, plans were made for two new power houses of 220,000 kw. each, it being considered advisable to prepare for more than five years' growth. A location was therefore selected which would be suited to the many and great requirements of such an equipment. To supply fuel for an aggregate of 240,000 kw., or 350,000 hp., requires something like 4000 tons of coal per day, or 100 car loads. Inasmuch as the fuel has to be brought 200 miles by rail for the Chicago plants, a reserve supply of even four days, if held in cars, would mean four miles of track room for 400 cars. The coal strikes, which occur quite regularly every two years, however, frequently mean that no coal can be had from the mines for three months. Hence one of the demands of the new plant was that there must be sufficient storage for coal to carry the stations over a three months' interval—that is, storage room for 350,000 tons. The site of the new Northwest station was therefore chosen at a point on the north branch of the Chicago River, several miles from the Fisk and Quarry Street stations, where sufficient acreage for coal storage was available.

The boiler house is so designed and equipped that at no point in the handling of the great volumes of coal that daily passes through it, is it necessary to use manual labor. The boilers are arranged in rows of ten each, facing each other on opposite sides of a common firing aisle, so that one set of firemen and water tenders can look after twenty boilers. Each ten

boilers are served by a tile-lined steel stack, 17 ft. inside diameter and extending 275 ft. above the boiler-room floor. When completed the turbine room will be 290 ft. long with the five turbines spaced on 44-ft. centers. The first two turbines are of the vertical Curtis type, similar to those of the Fisk and Quarry Street stations, and are rated at 20,000-kw. capacity, with a steam consumption of 13.45 lb. per kw.-hr. at the most efficient load, namely, 15,000 kw. The additional units for this plant are expected to be of the horizontal type and may run in capacity to 30,000 kw. or more.

TECHNICAL DISCUSSION

COMMUNICATIONS UPON ENGINEERING SUBJECTS
TREATED IN PREVIOUS ISSUES OF THE JOURNAL

A RATE-FLOW METER

J. W. LEDOUX, in a written discussion on the paper by H. C. Hayes on A Rate-Flow Meter which was published in abstract form in the March issue of The Journal, said that the question of using the difference in pressure at the inner and outer diameter of a pipe bent to a curve has been considered by engineers for a considerable time past, but this paper, for the first time to the writer's knowledge, gives a rational discussion of the elements affecting the flow under these conditions.

Any form of meter of this kind, of course, depends on the true bore of the pipe. As a casting is always subject to considerable variation, machining is resorted to in all first-class forms of Venturi tubes. For Pitot tube measurements, resort is had to traverses and measurement of the diameter of the pipe in place. With the Venturi tube the coefficient of discharge is determined by experiment for a considerable number of sizes, so that the accuracy attainable at the present state of the art for ordinary velocities can be counted on with probably 1½ per cent. With Pitot tube measurements, the calibration of the Pitot tube itself is carefully determined by experiment in the same way, so that when the traverse of the pipe is once made, the results with a Pitot tube in the center of the pipe can be counted on for all mean velocities within the range of the apparatus, say from half a foot per second up to ten or more ft.

The simple formula for the flow in an inferential meter of any of these types including that described by Mr. Hayes is

$$H = c \sqrt{v}$$

in which

v is the velocity through the pipe or meter.

c is a constant coefficient.

H is the head.

For any form of Venturi tube, orifice, or Pitot tube, n becomes 2 and when c is once determined by calibration, it is used without change for all meters of the same class.

For the V notch weir n becomes 2.5.

For the rectangular weir about 2.3.

For Mr. Hayes' device n appears to be 2.2, but the question is whether, if his experiments were sufficiently extended, this value of n would not approximate 2. If this exponent cannot be counted upon as a constant under various conditions and sizes of vortex meters, the ap-

paratus cannot be considered satisfactory as a commercial proposition.

At first sight, it would seem that the large deflections for given velocities as compared with the other two devices would be an immense advantage, and that is true providing we had to do with mean velocities below 1 foot per second only, but the ordinary Venturi or Pitot tube meter is often required to give its greatest accuracy at velocities considerably above 1 foot per second, and for a Venturi tube with a ratio of two to one, the deflection for only 6 ft. mean velocity corresponds to about 10 ft. of water head, or say 10 in. of mercury head, and a meter requiring much more than this becomes cumbersome in size.

Mr. Hayes states in his Par. 17 that "Such a meter should not be greatly affected by fluctuations of pressure such as are always produced by feed water pumps, for the inertia of the vortical mass will serve to steady the gauge readings much as the fly-wheel does the motion of an engine." If that is the case then it is only necessary to use on the small pipes leading from any form of meter to the register, some inertia device of sufficiently large mass of heavier or lighter liquid than that to be measured, but there is a prevailing impression that any form of inferential meter, including the one under consideration, will not measure accurately if there is a violent fluctuation in rate of discharge, a condition that is frequently caused, for example, by a reciprocating pump, which is not connected with a large air chamber. If that is true, the defect obviously cannot be remedied unless the vortical mass can in some manner induce a uniform rate of discharge through the pump. This subject, however, has not been fully investigated.

The heretofore objections to metering water with these inferential types have not been due to the shortcomings of the Venturi tube but to the limitations of the registering devices. Mr. Hayes refers to several well-known devices, some of which depend on cams and others on the movement of shaped floats, and he concludes that the trouble with these devices is the necessity of a stuffing box which introduces so much friction as to interfere materially with the accuracy. The stuffing box, however, is the least of the difficulties, and with well-designed details, the results are approximately as good with the stuffing box as without, because the shaft connecting the inside and outside of the meter register is so small compared with the radius of the rack-pinion or sheave, that this friction is negligible. Any form of cam, however, introduces another kind of an error that is much more serious. Mr. Hayes would overcome all these objections by using the device shown in his Fig. 7 of the March issue of *The Journal* and of Fig. 16 of his original paper. This principle was investigated by the writer as far back as 1904, after which it was found that

Mr. Walter Ferris was really entitled to the priority of invention, although while illustrating the basic principle his disclosure did not show it in a very practical form for commercial use.

According to Mr. Hayes' presentation, the radius of the shaped vessel becomes infinite before the flow has reached zero, and therefore, this particular type of meter has a serious theoretical limitation, which makes it incapable of measuring with the same instrument from the highest to the lowest flows. In fact, it has the same limitations as the type using the parabolic cam, which is vertical to its axis at the minimum velocities.

The flexible tube introduces a very objectionable feature except where there is no pressure in the vessel, when it can be made of rubber tubing with thin walls, but the weight of the mercury in the cylindrical vessel must be externally resisted by some form of contrivance that operates in such a manner that the resistance is proportional to the weight. This means a spring, or a weight with a variable lever arm, or some other equivalent device. Every one who has had to do with springs knows how difficult it is to get them to act according to their theoretical law and retain their properties for any great length of time. Presumably Mr. Hayes would make vessel B of glass and have attached thereto a uniformly graduated scale, which would give true indications of the heights of mercury in terms of velocity within the theoretical range of the instrument.

The apparatus described for eliminating the effect due to temperature is ingenious but probably impracticable for commercial cases, and at any rate, the differences due to changes of temperature are not important in water measurements, because the errors due to the ordinary range of temperatures can be neglected, and where the meter is used for hot water, it can be adjusted for the desired temperature by simply changing the size of the pinion or sheave.

There are a number of ingenious and practical registering devices of great merit in experimental use that have never as yet to the writer's knowledge been publicly described or illustrated, and this is the line of investigation that seems to warrant the expenditure of inventive effort.

In passing, it would seem that Mr. Hayes did not write his article with the idea of having it easily understood by the practical man, familiar with ordinary mathematical processes. The writer has not checked up the mathematical results because it would seem that those with which he is already familiar are more simple and direct. It is always desirable to simplify such discussions so as to be within easy reach of the maximum number of investigators.

On the whole, the writer believes that Mr. Hayes deserves great credit for his effort and accomplishment.

FOREIGN REVIEW AND REVIEW OF PROCEEDINGS OF ENGINEERING SOCIETIES

ENGINEERING SURVEY

One of the unfortunate results of the present events in Europe is the fact that many of the engineering societies there have been forced to abandon their usual spring meetings at which valuable papers were formerly presented.

THIS MONTH'S ARTICLES

In the section on Air Engineering is abstracted a discussion of the advantages and disadvantages of various blowers for cupola service, in which, among other things, the author questions the wisdom of using a single blower for several cupolas of different sizes.

The economy and possibilities of the use of Diesel engines for ship propulsion is discussed, both generally and with reference to data collected by actual experience. The author apparently believes that while a Diesel engine is somewhat more economical than a steam engine, its economy, in view of some other disadvantages, is not sufficiently high to carry with it the promise of materially displacing the steam engine as a prime mover on the high seas.

An abstract of the article on ball-bearings in electric railway cars in Switzerland shows an interesting design of ball-bearing installation, especially on center bearing between the underframe and bogie of the cars.

Two articles are devoted to the subject of boiler explosions. One describes an explosion of a locomobile boiler and shows how an apparently good boiler may become exceedingly dangerous because of presenting possibilities of improper manipulation. The other article shows that boiler furnaces fed with lignite coal, rich in gas, may, under certain circumstances, act somewhat as a gas producer and lead to disastrous explosions.

The article on German progress in steam boiler firing, the beginning of which was abstracted in *The Journal* for March 1915, is continued in abstract in the present issue.

An interesting account of tests on inclined cables is abstracted from the Journal of the Engineers' Society of Pennsylvania. W. H. Phillips, in a paper before the Engineers' Society of Western Pennsylvania, gives some data on a new secret method of heat treatment of gears called the B. P. Process, as well as on heat treatment of railway gearing generally. This paper led to an interesting discussion partly abstracted in the section Engineering Societies. J. D. Berg describes a low pressure steam turbine installation for mill drive, of particular interest both on account of its engineering features and also because it is the only one of that kind in existence in this country and the second installed anywhere.

Alan E. L. Chorlton, in a paper before the Institution of Mechanical Engineers, discusses the question of convertible gas engines and shows the kinds of engines, and conditions, which particularly lend themselves to use with more than one type of fuel. Among other things, the paper describes the Clerk supercompression engine.

Particular attention is called to the paper by Charles H. Lees (Royal Society) on the Flow of Viscous Fluids Through Smooth Circular Pipes, which contains not only

interesting formulae but also presents a valuable discussion of the work previously done on this subject.

FOREIGN REVIEW

Air Machinery

ADVANTAGES AND DISADVANTAGES OF VARIOUS TYPES OF BLOWERS FOR CUPOLA WORK.

The article discusses the advantages and disadvantages for cupola service of various types of blowers, centrifugal, rotary, and reciprocating.

The output of centrifugal blowers or fans is dependent upon a definite cross-section of outflow at which they can attain their highest efficiency. If, at the same speed of rotation, the most favorable cross-section of outflow is changed, both the amount of air taken in and that delivered by the centrifugal blower change in accordance with a known law. These changes are considered by the builders of centrifugal blowers and by some foundrymen as an advantage, but there appears to be a prevalence of opinion that really they are disadvantageous because they oppose in an undesirable manner the changing resistances in the cupola.

In regard to rotary blowers (of the Root and similar types) their action in delivering a practically constant amount of air under all conditions, appears to work favorably together with the change of resistances in the cupola.

Previous investigations have shown that as far as the operation of the cupola is concerned, the amount of air delivered and the air pressure are the determining magnitudes for the blower. It would have been of considerable interest, therefore, to find out whether and in how far standardization of cupola blowers is desirable.

In regard to the measurement of air delivery in the case of cupola blowers, many tests have established that anemometers give indications which are too large, and measuring nozzles, indications which are too small. The measurement of air on the basis of pressure differences in a double nozzle does not seem to have been as yet widely introduced in cupola service. Air may also be measured by exhaust gas analysis, but that is hardly suitable for small foundries. The measurement of air pressure as done now does not satisfy even the desire for information as to whether the required amount of air goes through the cupola, but, as soon as we start to measure the air in the state of motion, there will be a greater impetus for more thorough regulation of cupola blowers which can now be effected in a number of ways, for example, by varying the speed of rotation, or cross-section of outflow (of blower or piping).

As regards regulation, centrifugal blowers seem to have an advantage over rotary blowers because the power consumption in the former is within certain limits nearly proportional to the air output. On the other hand, the centrifugal blowers have a disadvantage in that, especially when driven by belting or other indirect transmission, they admit of only a limited variation in the speed of rotation and a certain excess of air has to be wasted by blowing off, which represents a corresponding loss of power and money. We have very little or no information as to the magnitude of

the losses which occur in that or another type of cupola blower as a result of the regulation of air output, which is indirectly proved by the fact that often several cupolas of very different dimensions are served by one blower.

It may be possible that if the losses due to regulation were better known, it would have been found that in the end it pays better to provide each cupola with a separate blower suited to its dimensions; if this were done, there would be a strong argument in favor of centrifugal blowers because of their low space and foundation requirements, ease of location in close proximity to the cupola and their practically noiseless operation.

It must be borne in mind that in a cupola operation it was found to be of great advantage to work with as uniform an air pressure as possible; this is one of the characteristics of centrifugal blowers and makes unnecessary the installation of equalizing air tanks on the cupola, or collectors in the piping. The author believes that in the selection of a suitable blower it would be well, before making a decision, to answer the following questions:

1. Are the variable resistances opposed to the blast in the cupola, such as clogging of the nozzles, hard and loose formation of bed of the charge, variable heights of charge, etc., so well determined in practice that their influence justifies the preference for a rotary blower?
2. Are the losses in power caused through regulation, often amounting to from 30 to 50 per cent of the normal air output, so low that one can operate for years two ovens with one blower large enough to fulfill the requirements of the larger oven, without suffering great losses?
3. Do differences in efficiency and first cost constitute a basis for preferring one or another type of blower, or must the influence of internal resistances in the cupola be also taken into consideration?
4. How can we, in the most certain manner, determine the amount of air passing through the oven and the power usefully required for operating the cupola blower?

(*Vor- und Nachteile verschiedener Gebläsearten für Kupolöfen*, J. Trenheit, *Stahl und Eisen*, vol. 35, no. 4, p. 102, January 28, 1915, 2 pp., p).

Internal Combustion Engineering

LARGE DIESEL ENGINED SHIPS FOR MARINE NAVIGATION AND THEIR ECONOMIC POSSIBILITIES.

The article discusses the economy and possibilities in the use of Diesel engines for ship propulsion.

During the last three years, about fifty sea-going vessels have been either built or laid with Diesel engines as the propelling machinery. Nevertheless, engineers and shipbuilders are as yet by no means agreed as to the economy of this method of propulsion. At first sight, shipbuilders have been strongly influenced by the difference between the thermal efficiency of a triple expansion steam engine amounting to about 14 per cent, and the 38 to 40 per cent claimed for the Diesel engine. In addition to that, three years ago, at the time when the Diesel patents ran out, the prices of crude oil were very low and in this respect the entire proposition looked far more attractive than it does with the present prices of oil, nearly three times as high.

The question of economy of Diesel engined ships has to be considered in the first instance in connection with the kind of fuel for these engines. The main source of the fuel is

the Atlantic Coast of the United States, Pennsylvania, Ohio, Texas and the southern states. There are large supplies of oil in Mexico around Tuxpan, but Mexican oil is not very well suited for use in Diesel engines, particularly because of its high asphaltum and sulphur contents. California oil, while available at present, will probably advance considerably in price after the opening of the Panama Canal, and in addition to that, a combination of powerful European interests have lately obtained control of a production of from 300,000 to 400,000 tons of oil per year. As far as sea navigation is concerned, the Russian, Roumanian and Galician oils are not as yet of much importance, especially as the Russian oil is said to be unsuitable for Diesel engines. In eastern Asia, however, large supplies of oil of the Diesel engine quality are available.

Rieppel has found in his investigations on Liquid Fuels Suitable for Diesel Engines that the most convenient are high percentage gas oils and paraffin, but the tar oils and hydrocarbons with a heating value below 9,000 WE (16200 B.t.u. per lb.) and containing asphaltum cannot be directly used in Diesel engines. Of late, however, it has been found that oils with an asphaltum content not in excess of 26 per cent and sulphur content not in excess of 2 per cent and a state of fluidity at 4 deg. cent. can be used in Diesel engines provided they are free from water, mechanical impurities and give no material ash residue. As a rule, crude oil is only in the rarest cases directly suitable and clean enough for use in Diesel engines. It is usually the products of distillation, distilled from temperatures between 150 and 350 deg. cent. (302 to 662 deg. Fahr.) that can be used in an engine provided their asphaltum and sulphur contents are not excessive. Distillates of lignite coal tar, obtained particularly by dry distillation of tar, are very convenient for use in Diesel engines. Owing to their high contents of paraffin, these oils, when injected into the working cylinder at a temperature corresponding to a compression pressure of from 33 to 34 atmospheres, form an oil gas which ignites with extraordinary facility. Coal tar, however, because of its low hydrogen content can be burned in a Diesel motor only with considerably more difficulty, and to help that, to the coal tar from 5 to 10 per cent kerosene is added, or the oil is preheated. For sea navigation outside of Germany, coal tar has, however, little importance.

So much for the source of fuel; now as regards the economy and efficiency of Diesel engines as compared with a steam plant of the triple expansion type the following data may be of interest: They refer to two vessels, the *Saltburn* and the *Evestone*, both of the Furness Line. Both are comparatively small vessels of equal length, beam, free board and depth. The weight and machinery is in the case of the steamer 1280 tons (metric) and the motor ship, 1260 tons. The carrying capacity for the same water line is in the steamer 3080 and the motor ship 3100 tons. Excess of loading room in the case of the motor ship as compared with the steamer, 190 cbm. (6700 cu. ft.). Both ships were sent on the same trip. The steamer traveled at a speed of 8.7 knots and consumed 12 tons of coal per 24 hr. The Diesel engine vessel went with a speed of 8.66 knots and an oil consumption of 3.95 tons per 24 hr. This shows a ratio of oil consumption to coal consumption with the consumption of the auxiliary boiler used to drive the rudder engine taken into consideration, to be 1:2.88, and that shows that the ratio often in-

adoption of the otherwise less convenient direct-connected compressor.

As regards the carrying capacity of Diesel engine ships, the author states that in the first installations an effort was made to secure a high degree of reliability and the saving in weight was therefore low. Later on, however, savings in capacity were effected; thus between the steamer *Santa Anna* (6400 tons) and the motor ship *Monte Penedo* (6410 tons), the latter had the extra carrying capacity of 450 tons. It must be borne in mind, however, that this difference includes the difference between the bunker contents of coal and oil amounting to 357 tons, so that the proper decrease in weight

The first cars provided with ball-bearings were placed on the Montreux-Oberland Railway in 1910—two 4-axle second-class cars, with bearings made by Schmidt-Roost, of Oerlikon, Switzerland. In 1911 seven more 4-axle cars, among them a diner, were equipped in a similar manner. The results were so satisfactory that the axles of all the new motor cars, passenger trailers and freight cars were equipped with ball-bearings, and at present the line has 39 cars so equipped. In new orders for rolling stock the application of ball-bearings was not limited to the axle journals, but for the first time in Switzerland, they were also introduced between the underframe and bogie of 4-axle cars. This arrangement,

FIG. 1. BALL BEARINGS ON ELECTRIC RAILWAY CARS

of the motor ship with the bunkers empty, was only 58 tons. The loading space saving in the ship was also very modest and amounted to only about 1.97 per cent. (*Die Grossdieselmotorshippe, ihre Wirtschaftlichkeit und ihre Zukunft*, Wm. Scholz, *Zeits. des. Vereines deutscher Ingenieure*, vol. 59, no. 5, p. 86, January 30, 1915, 7 pp., see).

Railway Engineering

BALL BEARINGS ON ELECTRIC RAILWAY CARS

The article describes tests made on the use of ball-bearings in various connections on railway rolling stock and the results obtained. Its interest lies in the fact that in the test described, a wider application of ball-bearings has been made than is usually the case.

shown in Fig. 1A, was particularly convenient on this line with its numerous and very sharp curves which had to be handled by comparatively long cars. The results were perfectly satisfactory, smoother runs being obtained on curves of small radii.

Then a new step in the same direction was taken, and on two new motor cars, the motor shafts were also equipped with ball-bearings, and altogether eight motors were so equipped, each of them having the remarkable (for narrow-gage) average output for one hour of 114 h.p. While there never was any trouble with the ball-bearings in axle journals and between the underframe and bogie, the ball-bearing arrangement in the traction motors, where the designer was very much limited by the space available, has caused some

trouble at first, but worked perfectly later, notwithstanding the very high pressures on the bearings and the violent lateral shocks due to handling sharp curves with low-lying motors having no spring protection laterally. This is particularly so, as the motors run at 1660 r.p.m., corresponding to a maximum speed of run of 45 km. per hour, with a wheel diameter of 900 mm. (35.4 in.) and a ratio of gear transmission of 1:6.286.

Fig. B shows the way the motor armature shaft is located in its ball-bearings. Attention is here called to the spherical hollow-cut in the casing of the bearing which permits the rings holding the balls in place, a certain amount of motion, to take care of the bending of the shaft, and also an automatic adjustment without any jamming or one-sided pressure.

An interesting novelty in the application of ball-bearings

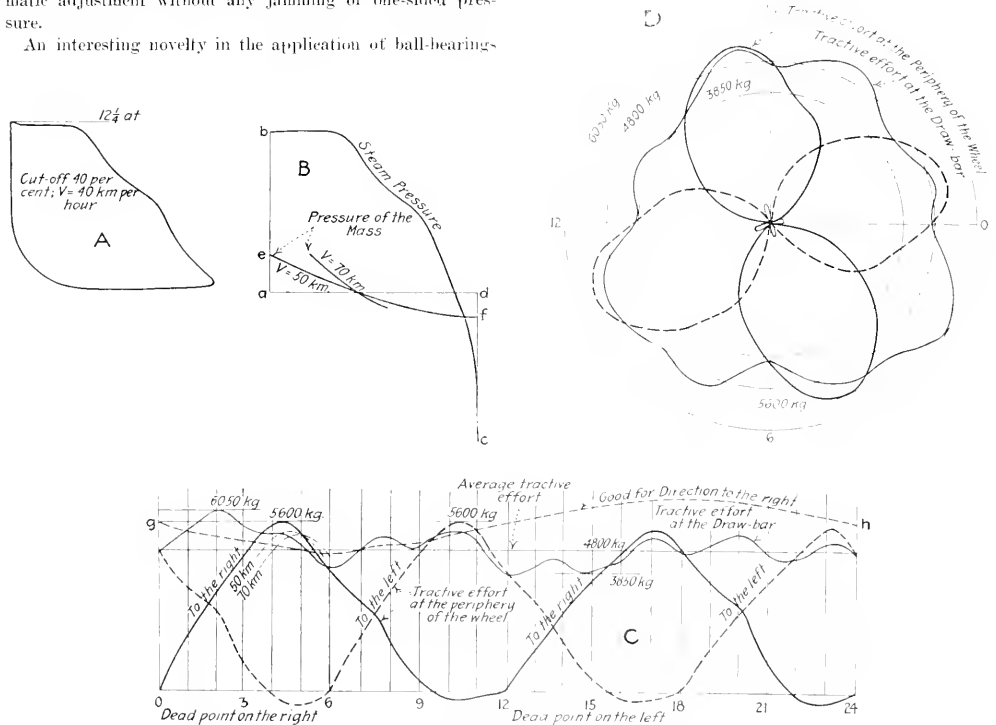

FIG. 2. A STEAM DIAGRAM, B OVER-PRESSURE DIAGRAM, C LINEAR PERPENDICULAR FORCE DIAGRAM OF A TWIN STEAM LOCOMOTIVE, D SAME AS C, IN POLAR DIAGRAM

is represented in the platform bogie shown in Fig. C. Out of the three bogies serving for the support of standard cars, weighing a maximum of 30 tons, two were equipped with sliding journals and a third with ball-bearings—Fig. C. This bogie is provided with rigid wheel axles, rigidly connected with the bogie, and the wheels loosely set on the axle and running on ball-bearings. It is said that this construction not only has the advantage of having a low internal resistance, but results in a soft and free of friction handling on curves, because the two wheels of the same axle can rotate independently one of the other.

In order to compare as precisely as possible the natural resistances of the two different types of bogies, experiments

were carried out in June 1914, with the registering dynamometer inserted between the bogie and the motor car. In order to be able to compare better with each other, the results obtained, without their being affected by the difference of the weight of the bogies, the total weight of the loaded trucks was the same, 26 tons, in all test runs. Nevertheless, because of continuous vibration and numerous curves following one after another, and also because the dynamometer had no device for damping, no claim to absolute precision is made here. A somewhat more reliable state of equilibrium appears to have been maintained, however, on a straight line stretch about 250 m. long and the record of the dyna-

nometer showed there a natural resistance of 5.3 kg. per ton (metric) with a slide bearing and 2.3 kg. per ton with ball-bearing.

A further serious argument in favor of ball-bearings is that first they have to be lubricated approximately once in six months as compared with 10 to 15 days in the case of a motor or passenger trailer car equipped with slide bearings, and further, that the life of the ball-bearing is from 10 to 15 years as against the life of a slide bearing of about two years. (*Erfahrungen mit Kugellagern im Betriebe der Montreux-Berner-Oberland-Bahn*, R. Zehnder-Spoerry, *Schweizerische Bauzeitung*, vol. 65, no. 5, p. 49, January 30, 1915, 4 pp., 1 fig., etc.).

UTILIZATION OF ADHESION WEIGHT IN STEAM LOCOMOTIVES.

The article discusses the utilization of adhesion weight in the case of steam locomotives, and the proper design of locomotives.

The author claims it to be inadmissible to use as a measure for the determination of the adhesion, the sum of rotating forces on the right and left drivers. He states that it is not safe to rely on what is known as "starting diagrams." There is no such thing as a starting diagram proper. If a locomotive were to start twenty times, the first set of indicator diagrams would come out different in every case in accordance with the crank position at starting, position of the throttle, the experience of the engineer, etc. The diagrams which the author uses, are not starting diagrams proper, but have been taken at average speeds, say 20 km. per hr., that is, during the period of acceleration of the train, and even such diagrams are not fully sufficient for the determination of the utilization of adhesive weight.

He discusses further the interesting question of the behavior of a steam locomotive as compared with that of an electric locomotive during the period of acceleration. In Fig. 2A is given a steam diagram for a cut-off at 40 per cent. Although it has been taken at 40 km. per hr., the throttle losses are so slight that it might be good for 10 to 20 km. per hr. just as well. At the low velocities of 10 to 20 km per hr., the action of the pressure of masses on the crank pin can be neglected and the forces acting, in the direction of the axis of the cylinder, on the driving pin at various positions of the crank can be obtained from the ordinates of the over-pressure diagram *abcd* in Fig. 2, from which, in the usual manner, the diagram of the peripheral forces can be drawn, with proper consideration of the finite length of the driving rods. Such diagrams are shown in Figs. C and D. In Fig. C, the pulls acting on the right and left wheel rims are plotted as ordinates over the developed wheel circumference.

Owing to the elasticity of the axes, it is not permissible for the purpose of determining the value of friction of wheel against the rail itself, to add together the values of forces acting on the right and left wheels and then count them as the adhesion draft referred to the axes or an ideal wheel. As a matter of fact, the value of friction draft does not have to be considered at all as far as the utilization of adhesion weight on a wheel is concerned. In Figs. C and D it is plotted as a thin wavy line with a maximum value of 6050 and a minimum value of 3850 kg. At the same time, the maximum value of the tractive effort never coincides with the maximum value of utilization of adhesion weight on the wheels since the maximum peripheral force on the driving axis is distributed fairly uniformly over the right and left wheel groups. (It varies from 6050 kg. to 3250 or 2800 kg.). The average value of the tractive effort, as shown in Figs. C and D, can be taken at 4800 kg. and it has the same average value in the electric locomotive with rod drive used for comparison with the steam locomotive. If in the electric locomotive direct current is used, then the tractive effort is of constant value throughout. With polyphase current, because of the overlapping of phases, it is nearly constant, while with single phase it varies quite considerably. In the first two cases, the average tractive effort of 4800 kg. represents also the maximum value acting on a single wheel

at the instant when the crank of the counter driving wheel is at its dead point, the minimum value being zero. It appears from Figs. C and D, therefore, that a two-cylinder steam locomotive with outside cylinders, as compared with an electric locomotive of the same average tractive effort, develops a peripheral pressure on the wheel, in so far as it affects the utilization of adhesion weight, 16.5 per cent greater and this result is good even when the conditions assumed do not favor the steam locomotive, viz., cut-off of 40 per cent and only a 6.3-fold length of driving rods. Several circumstances may, however, materially improve the condition of work in steam locomotives.

In the above example it was assumed that the locomotive had outside cylinders, and that the moments of torsion originated on one side of the machine in the driving and coupling pins, were transmitted directly through the spokes of the wheel on to the "friction coupling" between wheel and rail. But when there are inner cylinders and cranked axles, then the moments of torsion of one side of the machine will be transmitted not exclusively on to the wheels on one side, but, in accordance with the torsion of the axis, will be distributed in a non-uniform manner over both the right and left sets of wheels. As a result, the maximum stress which falls on one wheel, will be reduced. A limit in this respect is set by a locomotive with a Klien-Lindner driving axle, in which the tractive effort is transmitted exactly along the center of the axis on to the hollow wheel. In this case, the maximum tangential force on the circumference of the wheel is only about half as large as in an electric locomotive with rod drive and equal tractive effort. As far as the utilization of adhesion weight is concerned, the Klien-Lindner locomotive and the locomotives with two inner cylinders, and with three or four cylinders lying side by side, are all of them superior to electric locomotives, because tractive efforts which have to be transmitted by a single coupled set of wheels, do not reach quite as high maximum values.

The locomotive is, however, stressed up to the limit of friction not only during the acceleration of the train, but also at comparatively low velocities, especially when pulling up-grade. For how long and how often adhesion force should be used in driving at higher speeds is purely a question of boiler and grate utilization. Locomotives used on uneven grades have to be prepared to stand particularly high stresses in this regard. At high speeds, the action of pressure of the masses on the driving pins (the magnitude of which is indicated by the ordinates of the area, *adfe*, Fig. B) must not be neglected. The ordinates of the diagram *ebcf* show the piston pressures acting on the driving pin when the speed is 50 km per hr. and Fig. B permits one to estimate the piston pressures also at speeds up to 70 km. The action of the pressures of masses is of an equalizing nature; that means that because of it the piston pressures become more and more uniform, and the same applies to the tractive efforts acting on the periphery of the wheel, as indicated in Fig. C by the dotted curves between the ordinates 3 and 6. Since the pressures of masses do not affect the average tractive effort of 4800 kg., the excess of peripheral force action on the wheel in steam locomotives is less than the maximum of 4800 kg. of electric locomotives. Strictly speaking, the steam diagram of Fig. A is not precisely correct for velocities of 50 and 70 km., since greater throttling losses appear at higher velocities. The latter, how-

ever, are so dependent upon the dimensioning of the organs of steam distribution that in this connection it cannot be considered as of material importance.

One more point has to be mentioned, and this is that under certain conditions, the steam locomotive is at a disadvantage as compared with the electric locomotives, in as far as the utilization of adhesion weight is concerned, and this disadvantage lies in the fact that the centrifugal forces of the balancing masses of the counterweights oppose the action of the adhesion weight. In the two-cylinder locomotive, however, with the driving gear running in counter-directions and in the four-cylinder locomotive of the Bories type, the equalization by counterweights is omitted and therefore the utilization of adhesion weight is not affected at all.

The author comes to the general conclusion that in steam locomotives there are considerable variations in the utilization of adhesion weight not dependent upon the construction proper. Theoretically, however, it may be assumed that the steam locomotive utilizes the adhesion weight just as well and perhaps better than the electric locomotive and that the parts of a steam locomotive serving for the transmission of power are more favorably stressed than the mechanical parts of the single-axle polyphase-current electric locomotive.

Die Ausnutzung des Reibungsgewichtes bei der Dampflokomotive, Dr.-Ing. Ludwig Schneider, *Dinglers polytechnisches Journal*, vol. 329, no. 50/51, p. 696, December 19, 1914, 5 pp., 4 figs., t).

Steam Engineering

GAS EXPLOSIONS IN LIGNITE FIRED BOILER PLANTS.

The article discusses explosions of gas in lignite fired boiler plants and methods of their prevention.

In German practice, several accidents are recorded of gas explosions in the flues of steam boiler plants. Such a case, for example, occurred in a rolling mill boiler equipped with a step grate. In that case, a lignite, rich in gas, was used and the fireman was in the habit of piling large masses of fuel over the bed. Once, shortly after he had loaded up the grate in that manner, there was a tremendous explosion which did a lot of damage to the plant.

Another case of considerable interest occurred, also in a German plant, where a new boiler had been installed and was being heated up. At first a wood fire was lighted on the grate of a Ten-Brink furnace. Over this wood fire the fireman piled up a heap of dry Bohemian nut lignite, high enough to reach the tip of the funnel of the hopper, the damper being wide open. As soon as the coal was piled up in this manner, it was noticed that the draft fell off and smoke began to come out of the grate. This was followed suddenly by a tremendous explosion which did a large amount of damage and, among other things, destroyed the boiler setting.

After things had been put back in shape, another attempt to fire up the plant was made, and the next day there was a second gas explosion which did, however, somewhat less damage than the first. As the concern which contracted for the installation of the boilers was under the impression that these accidents were due to lack of sufficient draft, they have replaced the old smoke stack (22 m. high and 0.5 m. wide), with a new smoke stack 35 m. high and 0.75 m. in diameter), even though with the old smoke stack there was a draft of more than 11 mm. of water. The hoped-for results, how-

ever, failed to materialize, as several days after operations were resumed, there occurred a third explosion more violent than any of the preceding ones, which indicated that the cause should be looked for elsewhere than in the conditions of the draft.

Further observations have finally shown that the inclination of the grate of approximately 48 deg. was too steep for the kind of lignite used. Accordingly, the fuel used to slide down without being consumed and in this way covered up the fire so that what occurred was to a large extent similar to the case of the fireman in the first explosion, who heaped too much fuel on the fire. A new grate was put in with an angle corresponding to the angle of repose of the lignite and no more trouble was experienced.

The German associations for boiler inspection have collected quite a large amount of material on this subject and the fundamental rule which they developed is *to look out that the boiler furnace should not become practically a gas producer*. The firing arrangements should be adapted to the kind of fuel used and the fireman should be particularly cautioned to maintain the entire bed uniformly covered with fuel to a height that will permit the flame to break easily through. If this is done, all the gases developed can rapidly pass out and be burned above. The thickness of the bed depends upon the kind of fuel used. If it is in large lumps so that both the flame and gases can easily pass through it, and of a nature of coke, the bed may be thicker than with fine material rich in gas.

The article goes on to point out measures similar to the above. Among other things, the author recommends opening the fire door, ash door and smoke stack damper from time to time and to admit as much air as possible into the flues, so as to remove any dangerous gas mixtures, or at least to lower their temperature and change their combination. Where the boiler has dead corners in which hot gases may accumulate without being subject to the action of the smoke stack draft, proper openings should be provided to drive such gases into the smoke stack. It is also a good idea to place in various parts of the flues, safety valves opening outward so that, if a gas explosion should occur, its action would be less destructive to the general system. (*Verhütung von Explosionen bei Braunkohlenverfeuerung in Kesselanlagen*, P. M. Grempe, *Braunkohle*, vol. 13, no. 46, p. 614, February 12, 1915, 3 pp., p).

EXPLOSION OF A LOCOMOBILE BOILER

The boiler shown in Fig. 3A which exploded in October 1913 in Gehelesberg (Upper Bavaria, Germany) was made in Germany in 1873 and licensed for a working pressure of 5 atmospheres absolute. Its heating surface was 7.2 sq. m. (77.4 sq. ft.), the area of the horizontal grate built-in in the fire box, 1.43 sq. m. (15.38 sq. ft.), a total volume of 108 cu. m. (3814 sq. ft.), with a steam space only 150 mm. (5.90 in.) high. The sheets of the boiler were connected with each other by simple lap riveting. The locomobile was used for farm purposes.

On the day of the explosion, it was to be used for driving a threshing machine and was being heated up after a stop of 14 days. The heating was started at half past five in the morning and at half past six the boiler showed a pressure of 2 atmospheres. The attendant considered this pressure too low and started to heat it faster; soon after, the

boiler exploded with a tremendous noise, throwing large parts at a considerable distance. The water gage was not broken but much damage to property was caused and two men were injured.

The boiler was subjected to an internal inspection in April and while inward bulging was observed in the crown sheet, it did not appear to be of particular depth. It was again inspected, externally, in the fall and no dangerous developments were found. As to the causes of the explosion, it is rather difficult to form a precise opinion because the parts were not inspected until five days after the explosion when the pieces of the boiler were thoroughly covered with dirt and rust. Since, however, it was found that the crown sheet remained in practically the same state as when it was inspected before and a certain amount of scale was still sticking to the fire box walls and fire tubes, it seemed to be clear that the explosion was not caused by lack of water.

The state of the plates was such as to make it impossible to determine whether the explosion was due to previous cracks. It might be possible that it was due to excessive pressure although the attendant states that immediately

with water. It is possible old cracks, not previously noticed, may have contributed to the weakening of the shell. (*Explosion eines Lokomobil-Dampfkessels*, Müller, *Zeits. des Bayerischen Revisions-Vereins*, vol. 18, no. 23, December 15, 1914, p. 211, 2 pp., 5 figs. dp).

COMMUNICATIONS FROM THE CHEMICAL LABORATORY OF THE BAVARIAN ASSOCIATION FOR BOILER INSPECTION

Feed water with high soda or mud content tends to form wet steam especially in heavily loaded boilers. In such cases, and particularly where the feeding of the boiler is intense, some of the boiler contents, that is, water and mud, are easily carried away with the steam. Mud is particularly easily carried over into the steam piping if the feed water contains oil. In that case, the oil drops either settle on the deposited particles of mud or, where the oil contains saponified particles, it helps to form foam. The mixture of boiler mud with oil has a very low specific weight, and floats on the surface of the water, while if it were free from oil, it would settle in the boiler at the spot where the movement of the water is least.

FIG. 3. LOCOMOBILE BOILER WHICH EXPLODED

before the explosion the pressure indicated was only 2 atmospheres. This may be true but it appears rather unusual that after a heating of only one hour in the early morning, there should be a pressure of 2 atmospheres after the boiler has been kept cold for a long time and especially in view of the fact that the water must have been quite cold (4 to 5 deg. cent. — 39.2 to 45 deg. Fahr.). The attendant, further, tested the water gage before starting the boiler and found that the water flowed through all of the cocks. One may conclude from this that, by way of precaution, he overfilled the boiler with water and if such was the case, it might be possible that the water, because of its expansion when heated, filled up almost entirely the very small space remaining in the boiler, so that when the steam began to form, the pressure on the boiler walls began to increase very rapidly. When the manometer showed 2 atmospheres, this pressure appeared too small to the boiler attendant for starting the engine; he continued to heat it and a few minutes later the boiler exploded. These few minutes may have been quite sufficient to raise the pressure to such a height as to cause at somewhat weaker places a rupture of the boiler walls and as soon as this happened, the superheated boiler water suddenly expanded into steam and thereby produced the explosion. It is believed, therefore, that in the final account, the explosion was due to excessive filling

In a steam plant, considerable amounts of mud have been carried over by superheated steam into the pipes and heating elements and there have caused considerable trouble, which required tedious cleaning. In addition to fresh water feed water containing oil was also used. The analysis of the whitish deposit in the pipes and radiator elements, made in the chemical laboratory of the Association, showed the presence of considerable amounts of calcium dioxide but only 1.7 per cent of oil. When dried, this mud was very light and voluminous, 100 g. occupying a space of about 450 cm.

In another case, in a superheater steam boiler of a locomobile, purified feed water was carried over into the superheater because of the large content of soda and the intensive feeding, and in the superheater was converted into steam. The salts in the water in the form of fine dust, reached the steam chamber of the engine and there, together with the cylinder oil, formed a black-grey crust 2 to 3 cm. (0.78 to 1.18 in.) thick. At first oil was blamed for this crust formation, but laboratory investigation proved beyond doubt that it was due to the action of the boiler. A quantitative analysis of an average sample of the crust gave the following results (in per cent):

Sodium carbonate.....	48.0	per cent
Sodium sulphate.....	26.5	per cent

Sodium chloride.....	6.7	per cent
Original material soluble in toluol.....	3.0	per cent
Material soluble in toluol in the mass obtained by decomposition with hydrochloric acid of the residue after the first extraction with toluol	1.1	per cent
Carbon from decomposed cylinder oil.....	7.5	per cent
Calcium carbonate.....	0.7	per cent
Silicic acid.....	0.16	per cent
Iron oxide.....	0.13	per cent
Moisture and traces of magnesium as residue..	6.21	per cent

This shows that the crust formed in the steam chamber of the locomobile consisted to the extent of nearly 81 per cent of easily soluble salts which are always present in superheated feed water made from purified water, viz., soda, sodium sulphate and common salt. The carbon comes from the cylinder oil decomposed by continued action of superheated steam. The parts soluble in toluol are partly non-decomposed lubricating oil and partly asphaltum materials either initially present in the oil or formed in it through the processes of pitch formation. (*Mitteilungen aus dem Chemischen Laboratorium des Vereins, Zeits. des Bauverischen Revisions-Vereins*, vol. 18, no. 23, p. 213, December 14, 1914, serial article, not finished. c.)

GERMAN PROGRESS IN STEAM BOILER FIRING.

A continuation of the article describing new types of grates and steam boiler firing systems abstracted in *The Journal*, March 1915, p. 185.

C. Fischer of Frankfurt-on-Main uses a pair of roller levers for driving the fuel-throwing shovel of his stoker. (German patent No. 279,978). During the rolling, motion initiated by the driving lever is transferred to the driven lever in such a manner that the latter moves with a greater amount of force but at a lower velocity, on account of which, although the force of the motion decreases, the motion itself is accelerated all the time. Fig. 4A gives a diagrammatic side view of one of the designs of this drive. The device for moving the shaft *a* of the fuel-throwing shovel consists of two roller levers *b* and *c*, of which the first is the driving one resting on the shaft *d* while the other one is a driven lever and moves the shaft *a*. In the frame *e*, there is provided a bell crank *f* which is moved by the crank disc *h*, through the rod *g*. The bell crank *f* acts directly on the driving roller *b*. In order with such an arrangement to secure a certain amount of adjustability, pedal *i* of the bell crank is made adjustable by means of a hand wheel. In order further to secure continuously variable drive of the lever *b* and through that, of the fuel-throwing shovel, the lever is located on an eccentric *k*, rotatable by means of a locking device *l* and *m*. The motion of the wheel regulating the admission of the fuel to the fuel-throwing shovel, resting on the shaft *n*, can be varied in a similar manner by locating the locking device *o, p*, on the shaft *n* and by connecting it, by an intermediary lever *q*, or the crank disc *h*. The driving lever *b* can also be designed as a laminated plate spring so as to secure a certain amount of elasticity.

A peculiar stoking device has been obtained by J. Hierold of Erfurt (German patent No. 279,469). The fuel is delivered to a rigid plane grate from a hopper located so as to secure a predetermined height of fall, and is moved forward by a circular brush engaging into the grate openings. Fig. B gives a vertical longitudinal section through this stoker

as built-in in a fire tube boiler. The grate is here supported by a rigid frame *f* in such a manner that the circular brush *a* moves on the upper part of the grate from the front to the rear end, and on the lower side from the rear end towards the front end, without striking any part of the grate. To make the disc *a* move, there is located on both sides of the grate frame a chain drive protected from the action of the fire. The chain drive and the fire plate *b* extend somewhat forward of the boiler front wall. On that part is delivered the fuel from the hopper *c*, through a height of fall regulated by the valve *d*. The baffle plate *g* serves to limit the extension of the fire and to protect the hopper.

In draft regulators which regulate the draft in accordance with the steam pressure, it is a usual practice to employ water under pressure for actuating the regulator valve. In such a case, the steam pressure acts on a membrane through a column of water of condensation which accumulates over that membrane, and the latter, in its turn, actuates the valve in the piping containing water under pressure. There is, however, a difficulty in such an arrangement due to the fact that the column of water of condensation, owing to its friction against the walls of the piping, opposes the impulses which have to be transmitted to the membrane, this resistance being proportional to the steam pressure exercised on the column of water. As a result of that, the membrane begins to move only when the variation in the boiler pressure is greater than the frictional resistance of the water column in the piping which contains the water of condensation.

The Apparatebau- und Herdkessel- Industrie Karl Alt & Paul Jerome in Strassburg i. E., Germany, has patented (German patent No. 277,331) a draft regulator which is claimed to be immune from this source of trouble. Inserted in the piping between the membrane and the boiler, there is a device which reduces the boiler steam pressure before it begins to exert a pressure on the water column acting on the membrane, and this reduction occurs in such a manner that to certain pressure variations in the boiler, there correspond greater pressure differences on either the water column or the membrane; further, shocks uninterruptedly following one after another produce a certain restlessness in the membrane, which renders harmless its inertia with respect to motion. By means of these two separate actions, a high sensitiveness of the membrane is secured and it is made to respond to pressure variation of $\frac{1}{100}$ of one atmosphere. As a result, should the pressure rise by $\frac{1}{100}$ of an atmosphere over the working pressure, the slide damper is immediately closed and when the pressure falls by $\frac{1}{100}$ of an atmosphere the slide damper is opened.

In order to ensure that, where steam pressure draft regulators are used, the opening of the fire box door should bring about the closing of the slide damper, J. Matter has designed the device shown in Fig. C. (German patent No. 276,859). The slide damper *e* is suspended from the hydraulic piston *c*, loaded with the weight *d*, the piston moving in the hydraulic cylinder *b* connected with the pressure tank *a*. The admission of water to tank *a* and cylinder *b* occurs through the valve gear operated by a rod dependent upon the opening and closing of the fire box door. Beside the cylinder *b*, there is provided also a steam cylinder *g*, supplied with steam under boiler pressure by which the piston *h* is raised by the steam pressure against the pressure of the spring *i*, surrounding that piston. The piston *h* carries in its lower part a strongly built flange *l*, which overlaps the flange *k* on piston *c*. Since

both pistons are guided vertically in their guide rods, the piston *b* is carried away by the piston *h* and therefore the slide damper is adjusted in accordance with the steam pressure in the boiler. When the fire box door is opened, the piston *b* rises high enough to have the slide damper *c* entirely closed and after the closing of the fire door, comes back again to a position, the height of which is determined by the location of the flange *l* or piston *h* and which corresponds exactly to the steam pressure prevailing in the boiler.

Ch. Hülsmeier has devised a method of regulating the process of combustion by the weight of the fuel on the grate (German patent No. 277,332). One design of this rather complicated arrangement is shown in Figs. D, E, and F. The grate *a* is made freely oscillating about the point *b* and consists of a tuyere plate *c*, grate bars *d*, fire bridge *e*

and supplementary air piping *f*. The fire bridge *e* is connected by bolts or angle irons with *c*, in which are located the removable grate bars *d*. The end of the grate consisting of the bed *c* is made freely oscillating and rests on the shaft *i* which is kept in its position by the springs *k* and is balanced by the weight of the freely oscillating part of the grate. The shaft *i* is provided with a cam *h*, which in a normal state of operation keeps the valve *m* closed. When the grate is loaded with fuel, the tip *g* of the tuyere plate *c* presses so hard on the cam *h* that the cam *h* opens the valve *m* and admits steam through the piping *o* to the nozzles *n*, *n'*, etc. The amount of steam admission varies with the course of combustion and the load on the grate. The springs *k* are located on eccentric cams on the fire door *p* so that when the latter is opened, an additional tension of the springs is obtained which results in the valve *m*, i.e., the steam admission to the grate, being closed. The rate of air transmission through the layer of fuel varies as the load on the grate and the former may be utilized in order to obtain a still closer regulation by inserting in the separate air chambers a measuring pipe with several openings. This pipe may be filled with a liquid the level of which would vary as the draft, that is, as the resistance of the fuel bed. If this device for measuring the draft be filled with mercury and suitable electric contacts be placed in the glass walls, it would be possible to regulate automatically the air admission to the various sections of the grate (*Neue Patente auf dem Gebiet der Dampfkessel-Feuerung*, Pradel, *Zeits. für Dampfkessel und Maschinenbetrieb*, vol. 38, no. 6, p. 45, February 5, 1915, 2 pp., 7 figs., d).

FIG. 1. NEW DEVICES IN BOILER FIRING

fore quite different from those met with on a hoisting incline. The machinery includes a double 30 in. x 30 in. steam engine but the power is employed merely to start the cars moving, though occasionally it is necessary to use steam over points where loads do not sufficiently overbalance the empty side.

The article describes in some detail the arrangement of the cables. A cable is carried along the track on cast manganese steel rollers with rolled manganese steel axles cast in, the axles running in rough cast iron half bearings. After three years' service, the original manganese steel rollers show no apparent wear. The tensile strength per sq. in. metallic area in cable section has been found to be from 175,000 to 182,000 lb. while the actual tensile strength of the wires vary from 728,000 lb. to 751,000 lb.

The article describes fully the tests made on the cables.

SERVICE AND TESTS OF MAYARI INCLINE CABLES, James E. Little

The paper describes tests of inclined cables on an iron mine property in Cuba.

The Mayari mines in Cuba operate a rather unusual inclined cable railroad over which 50 ton capacity steel cars can be lowered in trains of three through a total vertical height of 1084 ft., the maximum grade being 25 per cent. These conditions of operation require a cable having a working strength of about 150,000 lb. The inclines are only for the purpose of lowering loads and the conditions are there-

The object of the tests was to ascertain the relative strength of the different cables when new, as well as the strength of used specimens, this information to serve as a guide in the operation of the incline. Tests of three cables delivered between December 1912 and October 1914 have shown that the last cable is about 3.5 per cent stronger than the average of its two predecessors.

To soften the cable in order to be able to cut it in Cuba, where the facilities for doing such work were naturally limited, it was annealed by a wood fire, at a point to be cut. When the socket was being placed on the specimen, this annealed end was not noticed and was not sheared off. Consequently, when tested, it broke at the annealed point 8 in. from the socket under the comparatively low tension of 216,200 lb., while the remaining part of the specimen showed a breaking strength of 451,900 lb. All broken wires at the annealed point showed an unusually high elongation and reduction. In other tests, it was noticed that new cable specimens break with very little warning, each part of the cable taking its proper proportion of the load; the breaking strength was, however, about 80 per cent of the total wire strength, which has proved that the cable was very carefully manufactured.

The article also contains detailed data of tests on the different wires used in cables. Illustrations are given reproducing the photomicrographs showing the condition of the worn surface of the cable wires magnified 50 diameters. It appears that in the manufacture of a cable for such a use, the great problem is the selection and treatment of material so as to reduce the hardening effect on the surface of the wire due to abrasive friction, to a minimum, without unduly sacrificing the tensile strength or flexibility of the cable (14 pp., 5 figs. *e*).

Recent Developments in the Heat Treatment of Railway Gearing, W. H. Phillips (abstracted)

Steam Turbine Mill Drive, J. D. Berg (abstracted)

Discussion on Tests of Large Reversing Engine and Rolling Mill (for abstract of original paper see *The Journal*, January 1915, p. 55)

RECENT DEVELOPMENTS IN THE HEAT TREATMENT OF RAILWAY GEARING, W. H. Phillips.

The paper discusses the manufacture of railway gearing, partly historically and partly by describing a new method of heat treatment called the B. P. Process.

The development of the railway motor gear in its various stages, (cast iron gear, malleable cast iron, cast steel four-spoke, cast steel six-spoke, forged steel, rolled, hammered and rolled, flexible gear) and the pinion is briefly described. After this, the author proceeds to a discussion of the method of heat treatment and its various processes. The most interesting part is that referring to the B. P. Process which is a secret process, the details of which the author does not state. From the information given, the B. P. Process consists of the following sequence of operations: annealing, machining, quenching and drawing. A careful selection of the raw material and the quenching operation constitute the main feature of the high quality of the product. It is claimed to produce a very hard material, of high tensile strength

without losing its ductility. The hardness tapers off gradually from the wearing surface to the center of the tooth.

In the discussion which followed, W. L. Allen stated that the B. P. Process was the outcome of years of research on the part of the Nuttall Company, which aimed to produce gearing having high surface hardness combined with great strength, and to obtain the refinement of structure at less cost than is possible through case hardening. The B. P. Process does not develop as efficient a gear as is brought about through case hardening, but the efficiency which is produced in this process very closely approaches that of the case hardened material and at so much less cost as to make the B. P. grade of gearing very much more economical for the average present day normal operative service.

The same gentleman stated that the Nuttall Company has made a great many experiments to determine the relative merits of pinions cut off forged and rolled bars as compared with pinions made from individually forged or pressed blanks and has found that in some cases the individually forged blanks produce a stronger and better pinion than those made from blanks machined from bars. He stated,

FIG. 5. DIAGRAM SHOWING THE LIFE OF CARBON STEEL IN REPEATED BENDING AT VARIOUS STRESSES

however, that it is his opinion that in pressed forging, the material is compressed at the center more than either in hammering or in rolling and the result is that a more homogeneous mass throughout is produced than in the hammered, forged or hot rolled processes. He stated also that some experimenting is being carried on with chrome-vanadium steel for gearing as well as manganese-vanadium steel entirely free from chrome and with the manganese content of about $1\frac{1}{4}$ to $1\frac{1}{2}$ per cent. No definite data have been obtained.

J. S. Unger said that a process was brought out several years ago to harden the teeth of cast steel gearing by coating the inside of the mould with powdered ferro-manganese. When cast, the temperature of the molten steel was high enough to form an alloy on the surface giving what might be called manganese steel which did not work very rapidly. Another process was brought out in which ferro-chromium was substituted for ferro-manganese. These teeth were very rough and sometimes full of holes and sometimes so hard that it was impossible to machine them. When a gear of this kind was put in service where sudden reversal or heavy starting loads were common, the hard alloyed surface would

sometimes shell off, causing trouble. At one time, experiments were made with the ferro-manganese gear in contact with two ordinary cast steel gears and the manganese gear outlasted the others three to one. While it showed very little wear, it wore out the special gears two or three times as fast as they would have worn out had the three gears in contact been of a softer material, so that the wear was simply transferred from one gear to the other.

W. R. Wigley made a series of tests on the resistance of steel to fatigue and the effect of heat treatment upon that resistance. Four grades of carbon steel were used in making the tests with carbon content of 0.014, 0.032, 0.061 and 1.02 per cent. The pieces were tested by bending them back and

as a natural elastic limit at stresses below which a steel will have infinite life against repetitions of load.

STEAM TURBINE MILL DRIVE, J. D. Berg

The article describes a low pressure steam turbine installation for driving two stands of 18 in. three-high mills of the Carpenter Steel Company at Reading, Pa.

This installation is to a certain extent similar to that installed about four years ago at the Calderbank Steel Works of James Dunlop & Company (near Glasgow, Scotland), where a low pressure steam turbine drives a three-high 28 in. plate mill. The Carpenter Steel Company formerly drove their three-high roughing mills by means of a 36 in. x

FIG. 6 STEAM TURBINE ROLLING MILL INSTALLATION

forth, thus starting up transverse stresses in the material. For each piece, the bending stress was computed and the number of cycles of bending back and forth counted. By changing the motion of bending in the various pieces of a series, it was possible to determine the life of the material at various stresses. When plotting the results (Fig. 5) a special plot was used; the ordinates were \log_{10} of the stress and the abscissae were \log_{10} of the number of cycles. From these curves, it is evident that at any stress, the higher carbon steels withstood the repeated stresses better than the lower carbon steel. In these tests, however, the loads were applied without impact, and impact might change the relation to some extent. One of the things upset by these experiments, in the speaker's opinion, was the belief in a natural elastic limit. The tests seemed to indicate that there is no such thing

36 in. simple engine at speeds of from 70 to 100 r.p.m. This engine operated condensing, but its economy was very poor. A little over a year ago a very careful study was made to better the general economy of operation and several methods were considered. The installation of a new compound engine for driving the roughing mills and a modern central condensing system were rejected because, on account of the wide fluctuations of load on the engine and the fact that the normal horse-power required was comparatively small, the first cost and economy of this type of installation were not attractive.

A low pressure turbine generator with condenser and motor drive for the mill would have worked out better had there been a greater demand for power for other purposes in the plant, but as the major part of the power would have

been used on the roughing mill, several disadvantages to this scheme were found, such as the high original cost of installation and a loss of from 15 to 20 per cent of the available energy in the steam through electrical generation and transmission. As a result of this consideration, it was finally decided to install a low pressure turbine with a double reduction gear connected to the roughing mill, and to obtain the steam supply for the turbine by running the finishing mill engine non-condensing.

The article describes in detail this new installation of which Fig. 6 shows the general layout. Very careful attention was given to the question of supplying dry steam to the turbine. In the 8 in. supply line, a special low pressure receiver-separator was installed, and between the separator and the turbine throttle there was a length of about 12 ft. of straight piping. In this 12 ft. of piping, made with a 10 in. inside diameter, a coil of 1 in. copper pipe was placed, to which a live steam connection was made at one end and the other end led to a steam trap.

Immediately before the low pressure throttle valve of the turbine, a Cochrane multiport flow valve was placed, the purpose of which was to prevent the loss of vacuum in case of failure of the pressure or failure of the exhaust steam supply. The following velocities were used in deciding upon the various pipe sizes: On the low pressure steam supply to the main turbine, 9500 ft. per minute; on the exhaust from the main turbine, 26,000 ft. per minute for the maximum condition and 16,700 ft. per minute for the normal condition; on the water line supplying the condenser 4.6 ft. per second on the discharge line and 3.5 ft. per second on the suction line. The exhaust line from the turbine driving the circulating pipe was figured for a future maximum velocity of 25,700 ft. per minute, and for the present condition, 15,500 ft. per minute.

The turbine is of the combination high and low pressure type and is designed to carry a normal full load of 350 h.p. with 120 lb. steam pressure at the turbine throttle and 3 in. absolute pressure in the turbine wheel case. In order to take care of overloads, the turbine is designed to operate with mixed pressure and, with steam at 3 lb. gage on the low pressure side and 120 lb. on the high pressure side, will carry 600 b.h.p. continuously. It is also designed to carry the full overload of 600 h.p. on high pressure steam only.

The turbine is of the De Laval multistage impulse type containing nine wheels with one row of buckets on each wheel. The turbine shaft operates at a speed of 5000 r.p.m. It is geared to 600 r.p.m. and this shaft in turn is geared to 100 r.p.m., the gears being of the double helical involute type with 45 deg. teeth. The pinion teeth in each case are cut from chrome nickel steel forged bands, the gears being made up of cast iron centers on which are shrunk rolled steel bands. The 600 r.p.m. shaft is supplied with a tachometer having a 4 in. circle with speed indications from 200 to 800 r.p.m. in 300 deg. of the circle. The entire cost of the installation consisting of the turbine, reduction gear, condenser piping, circulating pump, etc., delivered and erected, approximated \$25,000. On account of the better economy of the turbine, it has been possible to operate the plant on about 300 boiler h.p. less than before and to effect the saving of approximately \$15,000 per year in operation.

This turbine and the turbine at the Calderbank Steel Works in Scotland are the only two installations of their kind in existence.

In the discussion which followed, Jos. Breslove gave some data concerning the Calderbank Steel Works plant and especially the reduction gear used there. The reduction is effected through two gear sets bringing the mill shaft speed down from 2000 r.p.m. to 70 r.p.m. Flexible couplings are fitted between the turbine and the high speed pinion shaft and also between the first and second reduction gears. The low speed gear is keyed directly upon the shaft of the fly-wheel shaft which carries a 23 ft., 100 ton flywheel, supported between two heavy bearings (25 pp., 7 figs.).

CONVERTIBLE COMBUSTION ENGINES, Alan E. L. Chordlon

The author considers the question of design of convertible combustion engines, that is, engines which may be operated without essential alterations, on more than one kind of fuel.

At first sight, one might think that a combustion engine most ready to work on different fuels would be of the self-ignition type, with a cycle approximating to that of constant pressure and the only change necessary in going from liquid to solid fuel would be in the fuel injection device. In practice, however, owing to the difficulty with solid fuel injection, such a type would not prove workable and even when the fuel is first gasified, the results do not justify the complication. The problem of designing a convertible engine is better met by trying to combine known types for gas and oil in which good results are obtained at present and which, in general principles, show the same characteristics.

In the normal engines for both gas and oil, the chief difference lies in the degree of compression. There is no fundamental difference in engines for gaseous or liquid fuels except in their compression cycles, which shows that any schemes of convertibility must provide means whereby the requisite compressions can be obtained, but as there is a great gap between compressions of 100 lb. per sq. in. for a gas producer and 500 lb. in the case of crude oils, the tendency is, for practical uses, to combine the lower compression oil engine and the high compression gas engine and thus deal with a small compression pressure range. The desirable characteristics of a convertible engine are simplicity and reliability, high economy for each fuel, first cost as low as possible above that of the standard engine for each fuel, easy convertibility and as nearly as possible the same power for each fuel. The author divides all types of engines into three groups; first, engines of low compression and low power; second, engines of higher compression and higher power, and third, engines of maximum compression and high power.

Group 1. As an example may be taken the ordinary motor car engine, which has a compression up to 90 lb. per sq. in. and with slight modifications can run on several fuels. It is, however, designed for and works best on gasoline, fairly well but not so economically on city gas, requires very good kerosene and is not efficient at low compression with producer gas. If a more common kerosene or a good quality of crude oil is used, means must be provided whereby more heat is available for the ignition and combustion of the oil which can be done conveniently by the addition of an unjacketed portion to the cylinder end, when the engine becomes of the hot bulb type. Electric ignition is provided for gasoline as well as the kerosene, and good crude oil would be self ignited by the hot bulb. Fig. 7A shows such an engine for

small powers and it can be changed by unskilled labor from a gas engine working with a wood or coal producer to an oil engine, the governor requiring no adjustment for the full range of fuel. This type of engine is not suitable for any comparatively low powers and its range of fuels does not include anything heavier than good crude oil, and even its economy on oil is not high. *Group 2*, engines of higher compression and higher power, is represented by the Diesel engine with compression of over 500 lb. per sq. in. when using tar oils. Since a Diesel engine uses compression far exceeding the maximum compression for gas in a normally

- a* Engines working with a compression not exceeding 150 lb. for both oil and gas, and which may employ pocket firing with or without air injection for one, and electrical ignition for the other, or some combination, the smaller compression not involving material mechanical change of the parts.
- b* Engines working with a higher compression for oil than for gas, involving some modification of the combustion chamber by substitution of a part for oil as against a part for gas; otherwise maintaining the simplicity of both types.

FIG. 7 CONVERTIBLE COMBUSTION ENGINES

used type of engine and in addition requires an expensive high pressure air pump, there is no commercial advantage in working it on gas.

Engines with a moderate compression suitable for developing higher powers, range in compression between 150 and 300 lb., a low range being suitable for most forms of producer gas but not usually exceeded because pre-ignition of the compressed charge is more prevalent in very high compression gas engines.

Group 3. Engines with a moderate compression suitable for developing higher powers. This group may be subdivided into four classes:

- c* Engines obtaining the necessary change from gas to oil, by temperature control of the air charge, together with alteration of the valve settings.
- d* Engines employing the super-compression of Dr. Dugald Clerk, to control effectively thereby the compression required for either fuel.

In sub-division *a*, there are a large number of engines which are used only for oil but might, without material alteration, become effective for the use of gas, as for example, a 2-cycle Bolinder engine shown in the original article. In sub-division *b*, the outputs in general figures for the engines on oil and gas appear to be very similar and so are the

diagrams actually taken. The possibilities of this type of convertible engine appear therefore quite great; in fact an engine is being made at the present time in considerable numbers, to fulfill these conditions, (Figs. B and C). In both cases, it presents the ordinary features of the four-cycle, the only change involved in converting from oil to gas being in the combustion bulb of the oil engine in changing from an oil type to a gas type of piston.

As to class *c*, it is mechanically convenient but not quite efficient, as the author attempts to prove. In class *d*, the Clerk super-compression engine is a promising type for dealing with the variable compression problem of the convertible engine. In it, Fig. D, an extra charge of air or inert gas is added to the working mixture at the end of the suction stroke. By this "watering" of the charge much lower maximum flame temperatures are obtained and a higher mean cylinder pressure rendered possible. Further, the compression can be adjusted between wide limits. The conclusion at which the author arrives is that for powers up to say 1000 h.p., engines of the type shown in Fig. B and C are the most suitable as convertible engines while for the larger powers, when tandem engines and size and weight of removable parts become a problem, the Clerk super-compression type offers a hopeful possibility (15 pp., 13 figs.).

The Journal, No. 2, February 1915

The Steady Flow of Steam through a Nozzle or Throttle.
Professor H. L. Callendar (abstracted)
Standardization of Pipe Flanges and Flanged Fittings, John Dewrance (abstracted from Advance Paper in *The Journal*, March 1915, p. 189).

ON THE STEADY FLOW OF STEAM THROUGH A NOZZLE OR THROTTLE, Professor H. L. Callendar.

In the course of some experiments on the law of condensation of steam previously undertaken by the author, in which the temperatures of steam during adiabatic expansion and compression were observed with a very sensitive platinum thermometer in the cylinder of a steam engine, it was found that the index *m* of the adiabatic equation $PV^m = \text{constant}$ was very nearly independent of the pressure and temperature, and equal to 1.30. This result, at first sight, seemed discordant with the wide variations of the specific heat as shown by other experiments made at the same time, but was later on explained by the author's theory. The temperature measurements also showed that during rapid adiabatic expansion, the temperature of steam might fall appreciably below the saturation temperature, indicating a state of supersaturation in the cylinder. The practical importance of this state of supersaturation increases in proportion to the rapidity of the expansion, and becomes considerable in the case of expansion through a nozzle.

The object of this paper is to apply the equation for supersaturated steam to the problem of flow of steam through a nozzle or throttle.

The author objects to the formula commonly employed on various grounds, in particular, because steam cannot condense reversibly in the time taken to reach the throat of the nozzle, and the adiabatic equation for wet steam does not apply, therefore, to the maximum discharge determined by the state in the throat. Dry steam, when cooled by rapid expansion beyond the saturation point, does not condense unless suitable surfaces or nuclei are present to start the condensation, and when issuing from a jet, does not appear

cloudy for an appreciable space beyond the throat. It is physically impossible that any material condensation should occur in the time occupied in reaching the throat of the jet, which is generally of the order of 0.0001 second. The adiabatic equation which applies to the discharge, therefore, is not that of wet steam but that of dry steam, superheated or supersaturated. According to the author's equation, the appropriate value of the index *m* is 1.30, which agrees much better with observations of the discharge than the value 1.135 for wet steam commonly employed. The author points out, however, that it would not be justifiable to use this equation if it had not been shown by theory and experiment that it was thermodynamically consistent:

1. with the characteristic equation
2. with the cooling effect in expansion through a throttle
3. with the variation of the specific heat
4. with the equation of saturation pressure

and claims that the correspondence of his formula in all these cases is thermodynamically exact.

Equations for discharge of superheated or supersaturated steam according to the author's equations, the relation between *P* and *V* in the adiabatic expansion of dry steam, whether superheated or supersaturated, is

$$P(V-b)^{n+1} = \text{constant, or } P(V-b)^m = \text{constant,}$$

where $m = 1 + \frac{1}{n} = 1.30$.

The small constant *b* is the volume of the liquid at low temperatures, namely, 0.0160 cu. ft. per lb. or 0.001 cbm. per kilogram.

The corresponding expression for the total heat, $H = E + aPV$, is

$$H = a(n+1)P(V-b) + abP + B,$$

where *B* is a constant having the value 464.0 calories on the Centigrade system, or 835.2 B.t.u. on the Fahrenheit system, and *a* is the numerical factor reducing *PV* to heat units.

These equations may be combined with the equation of flow $kTX = W\Gamma$, and the thermodynamical relation $U_g = J(H_s - H)$, to determine the maximum discharge in $2g$ adiabatic flow, in the following manner.

The condition that the flow *W* is to be a maximum for a given value of the throat section *X*, or that *X* is to be a minimum for a given value of *W*, gives immediately the simple relation,

$$\frac{dU}{dV} = U/V$$

Eliminating $\frac{dU}{dV}$ by differentiating the equation $\frac{U^2}{2g} = J(H_s - H)$, we find

$$\frac{U^2}{JgV} = \frac{dH}{dV} = a(n+1)P + a(n+1)(V-b)\left(\frac{dP}{dV}\right) + ab\left(\frac{dP}{dV}\right)$$

Substituting the value of $\frac{dP}{dV} = \frac{-mP}{V-b}$ from the adiabatic equation, we obtain

$$\frac{U^2}{V^2} = \frac{amJgP}{V-b}$$

which is the exact expression for the velocity of sound in the vapor in the state (*P*, *V*), and differs from the expression usually given only by the small quantity *b*, which is commonly neglected. This term is theoretically required, even

in the case of hydrogen, the most perfect of all known gases, in order to explain the Joule-Thomson heating-effect, which is of great practical importance in the liquefaction of hydrogen. It is also required to explain the limit of compressibility of gases, and the increase of the velocity of sound for intense disturbances. Since, however, b is very small, and its exact value necessarily uncertain, the equation may be reduced to the simpler form,

$$\frac{V^2}{Jg} = amP(V+b)$$

which gives the throat velocity in terms of P and V in the throat.

The primary effect of supersaturation in the throat of a nozzle is to increase the discharge by about 5 per cent as compared with that calculated on the usual theory with a given throat area. The secondary effect is to cause an increase of entropy and volume when the steam becomes wet after passing the throat. The two effects require, for a given throat area and ratio of initial to final pressure, an increase of 6 to 8 per cent in the final area of the cone, or an increase of length of 3 to 4 per cent in the diverging cone for a given angle of divergence.

The effect of friction in the throat is to reduce the discharge by a small fraction, which appears to vary inversely as the initial pressure, and inversely as the throat diameter for similar nozzles. The order of magnitude of this fractional reduction, for a well-designed nozzle with smooth contours, appears to be given by the formula $\frac{1}{P_0 D}$, where P_0 is the initial pressure in pounds per square inch absolute, and D the diameter of the throat in inches.

The effect of friction beyond the throat increases with increase of velocity and diminution of final pressure, and may be estimated with some degree of probability by taking the percentage loss of heat-drop to be proportional to the heat-drop itself. The diminution of velocity and increase of volume due to friction may require an increase of 10 to 20 per cent in the final area, equivalent to an increase of lengths of 5 to 10 per cent for a given angle of divergence, as compared with the length calculated for the case of frictionless flow.

ROYAL SOCIETY

Proceedings, Ser. A, vol. 91, no. 623, London.

ON THE FLOW OF VISCOUS FLUIDS THROUGH SMOOTH CIRCULAR PIPES, Charles H. Lees

The article discusses the problem of the flow of a viscous fluid through tubes of circular section, especially smooth tubes, and in the introduction gives a review of the work previously done in this connection.

The Principle of Dynamical Similarity shows that for the flow of viscous fluids through pipes, if for a number of cases $\frac{rd}{\nu}$ has the same value (where r is the speed, d the diameter of the pipe and ν the kinematical velocity), then for the same cases $\frac{R}{\rho r^2}$ will have the same value, where R is the resistance per unit surface of contact of fluid and pipe, and ρ the density. Hence, if $\frac{rd}{\nu}$ be taken as the abscissae and R as the ordinates, every case of motion of a viscous fluid through a pipe will be represented by a point of the

diagram and all of the points will lie on a curve, if the principle is strictly applicable to such cases, or will cover a strip, the width of which will increase as the applicability of the principle decreases. The observations made by Stanton and Pannell on the flow of air and water through pipes show that if r , the velocity, be taken as the mean velocity over the whole section of pipe, the locus of the points in the diagram is a narrower strip, the width of which is only of the order of the errors of experiment and that for cases in which $\frac{rd}{\nu}$ is the same, the law of distribution of velocity

over the cross section is the same. The author proceeds to the determination of the simplest form of the function φ in $R/\rho r^2 = \varphi(rd/\nu)$ which would embody the results of Stanton and Pannell on one side and of Saph and Schoder on the other side. He obtains the following expression

$$R/\rho r^2 = 0.0009 + 0.0765 (\nu rd/\nu)^{0.75}$$

or

$$R/\rho r^2 [0.0765 (\nu rd/\nu)^{0.75} + 0.0009] = \varphi [0.0765 (\nu rd/\nu)^{0.75} + 0.0009 r^2]$$

and since this expression satisfies the principle of similarity, it has been shown to hold for the mean speed of flow of air and water through pipes of diameters between 0.3 and 12 cm. The constants of the above equation hold over the whole of this range at least, and probably this type of relation with a small change of the constants will apply over a much wider range. The author proceeds to the development of a formula expressing not R , the resistance per unit area of surface exposed to the fluid, but the fall of pressure $p_0 - p_1$ along a given length l due to it, by reproducing, side by side, the observations of Stanton and Pannell with a line showing the values deduced from his expressions and shows the close agreement between the two. The form of the final expression for the fall of pressure along the tube indicates that this fall will, for all velocities, be approximately proportional to the power of the velocity between the 1.65th power and the square, and that as the speed of diameter increases or the kinematical velocity decreases, the law of variation will approximate more and more closely to the second power. The further conclusions arrived at, are summarized by the author as follows:

- The difference of pressure $p_0 - p_1$ in dynes per square cm. between two sections distant 1 cm. from each other along a pipe of diameter d cm. through which a fluid, whose density ρ may be considered constant over the length l and whose kinematical viscosity is ν , is flowing with mean velocity r , cannot be represented by a single power of the velocity but requires for its expression a formula of the type $p_0 - p_1 = l \rho r^2 d^a (a - b (\nu' rd)^n)$ where a , b , and n are constants.
- To the extent to which the Principle of Dynamical Similarity is applicable to the flow of fluid in tubes, a , b , and n should be absolute constants applicable to all fluids and all tubes. Stanton and Pannell's results show that over a wide range $a = 0.0018$, $b = 0.153$ and $n = 0.55$.
- As the velocity and diameter increase and as the kinematical viscosity decreases, the pressure difference varies more nearly as $l \rho r^2 d$.
- The effect of temperature on the pressure difference decreases as the velocity and diameter increase and as the kinematical viscosity decreases. (8 pp., 1 fig. t .)

MEETINGS

MINNESOTA, FEBRUARY 12

The regular February meeting of the Minnesota Section was held in the offices of the St. Paul Gas Light Company at which Professor Stewart of the Minnesota Agricultural College gave a talk on Triangulation. He showed a number of slides which illustrated some work on Triangulation which he had done for the Government in some of the western states a few years ago.

ST. LOUIS, FEBRUARY 16

At a meeting of the St. Louis Section on February 16, a Committee was appointed to draw up a tribute to the late Col. Meier which is presented herewith:

In the death of Col. E. D. Meier, the local section of the Am. Soc. M. E. has lost a staunch supporter, adviser and friend.

Although the later years of his life were spent in New York he was a personal friend of many of us and admired by all for in him was combined a charming personality and rare technical ability.

He was a man of great originality and tireless energy, sparing not himself in the promotion of either his own ideas or those of others if he believed them good.

It was largely through his efforts that the local section idea was adopted. To him were due many improvements in his own particular field. Practically to him alone is due the inauguration of the most important movement ever undertaken by the American Society of Mechanical Engineers—the Uniform Boiler Code. If adopted this will do more than any other has done to promote safety from boiler explosions and the consequent conservation of life and property.

We have lost a valued friend, the country a good citizen and the profession an able engineer.

Respectfully submitted,

E. L. OHLE,
E. R. FISH,
EDW. FLAD,
Committee.

BUFFALO, FEBRUARY 25

At a meeting of the Buffalo Engineering Society on February 25, which the members of the Employers Association, the Chamber of Commerce and other Industrial Associations of Buffalo had been invited to attend, M. W. Alexander of the General Electric Company spoke on The Waste in Hiring and Discharging Employees. A very interesting statement that he made after working out the figures on the blackboard showed that in an average of thirteen plants, where 8000 employees had been added to the payroll during the year, over forty-six thousand had been hired and discharged in obtaining the increase of 8000. Based on a very conservative allowance, Mr. Alexander claimed that in the neighborhood of 26,000 of the total number hired were unnecessary, and that the cost of hiring and discharging this 26,000 amounted to over \$880,000. After presenting these figures, he gave a very complete explanation of the ideas which have occurred to him in studying this problem, which he has carefully worked out to avoid a considerable amount of this waste.

CINCINNATI, FEBRUARY 25

On the evening of February 25, the members of the Cincinnati Section gave a dinner in honor of Calvin W. Rice, Secretary of the Society. Following the dinner, Mr. Rice was introduced to the joint meeting of the Cincinnati Section

and of the Engineers' Club of Cincinnati, to whom he made an address describing the trip of the Society to Germany in the summer of 1913. Mr. Rice began by recounting the very careful preparations that were made for this trip. Before beginning the journey, members were furnished with itineraries giving a complete description of the various places of interest they were to visit. So painstaking was the preparation that members of the party knew not only the hotel for which accommodations were provided for them, but even the numbers of the rooms to be occupied. Mr. Rice described the life on board the ship, the meeting of the reception committee before European shores had been reached, the reception in Hamburg and a series of entertainments given by the engineers of Hamburg, Leipzig, Cologne, Düsseldorf and other cities. He described in detail some of the more remarkable establishments visited, illustrating their principal features by lantern slides.

BOSTON, FEBRUARY 26

A joint meeting of The American Society of Mechanical Engineers, American Institute of Electrical Engineers and Boston Society of Civil Engineers was held at Wentworth Institute, Friday evening, February 26.

Wentworth Institute was founded 3½ years ago for training workmen of the most competent and expert type, foremen and master mechanics, and has grown so rapidly that there are nearly 1300 pupils enrolled in its day and evening classes. This meeting gave an opportunity for the inspection of the new shops and laboratories which are admirably adapted to the special purposes of instruction for which they were planned, with most complete equipment. After a buffet supper the audience gathered in the assembly hall for the formal program upon the general subjects of the training and education of employees and the relation of the employer to his men and their education. There were over 200 present at the meeting and the addresses of all the speakers were very much appreciated. The several papers were as follows: The Responsibility of the Manufacturer for Training of Foremen and Skilled Workmen, by Walter C. Fish, general manager Lynn Works, General Electric Co.; The Employer's Side of the Problems of Irregular Employment, Henry S. Dennison, treasurer, Dennison Manufacturing Co.; Coöperation Between Employers and the Schools, William B. Hunter, director of Fitchburg Industrial School; The Economic Relation Between the Supply of Skilled and Intelligent Workmen and Unemployment of the Masses, Prof. Thomas N. Carver of Harvard University. It is expected to publish an account of these papers in a later issue.

NEW YORK, MARCH 9

At the monthly meeting of the Society in New York held on March 9, Dr. Hollis Godfrey, President of the Drexel Institute of Philadelphia, presented an address on the Application of Engineering Methods to the Problems of the Executive, Director and Trustee. Dr. Godfrey, who has served in his experience two municipalities, and a number of corporations having a large number of employees, has found that it is very necessary to be explicit, and to put various problems in writing so that the Board of Trustees or Managers could determine at a glance how to proceed. He has had to select the facts which were to be studied and after collecting and studying them, to translate them and

lastly to express them in such fashion that the executive can use them effectively for the different purposes for which an executive needs to use such material. Dr. Godfrey considers that it is peculiarly the duty of a consulting engineer concerned with facts to present them clearly and briefly in the three cases, in the case of the presentation to the board, in the case of the education of the staff and in the case of the education of the public.

Dr. Godfrey illustrated his paper with charts which showed graphically the problems with which he has had to deal and the results that he has obtained. A very interesting and lively discussion followed the presentation of the paper.

BUFFALO, MARCH 11

A meeting of the Buffalo Engineering Society was held on March 11. The meeting was addressed by Prof. C. F. Hirschfeld of Detroit on Interesting Features Involved in the Design of the Connors Creek Plant of The Edison Illuminating Company of Detroit. Lantern slides were used to show the geographical outline of the city of Detroit upon which the general distribution of power was indicated by the location of the sub-stations and the reasons explained for locating the new power plant at Connors Creek. Various views were also shown of the location of the plant and of the plant itself at the various stages of construction. The views were also shown giving a cross-section outline of the boiler house, turbine room and electrical power unit and a full explanation was given on the operating of the various parts of this machinery, which showed that a careful estimate has been made covering every detail of the power generation and consumption. All this has probably been worked out in more detail than any other plant which has been built in this country, and consequently the overall thermal efficiency of the plant as a unit is expected to equal if not to exceed any similar power plant which has ever been built.

About 150 members were present at the meeting and a large number of them entered into a discussion of Professor Hirschfeld's paper.

CINCINNATI, MARCH 18

A joint meeting of the Cincinnati Section of The American Society of Mechanical Engineers and of the Engineers' Club of Cincinnati was held on March 18. Theodore H. Schoepf, of the Westinghouse Company, gave an address on The Electric Commercial Vehicle. The speaker confined his remarks entirely to electric trucks. He began by describing the conventional design of the electric truck, and illustrated by slides the position of the battery box, the motor, the gearing of the latter, the steering gear, and the location of the brakes. He stated that the 1000 lb. and 4000 lb. trucks were the most popular, and that the use of such trucks was growing by leaps and bounds. After showing by various views and line drawings, the conventional design of the electric truck, some interesting departures from the conventional design were illustrated and discussed. A balanced-drive truck, in which gears are contained within wheels with solid webs and the entire motor and differential are contained in a hollow cast rear axle, was given considerable attention.

The speaker dwelt at length on the economy attending the use of electric trucks, quoting liberally from statistics tabulated in Chicago, Boston and New York. The range of

speeds and distances per day within which the electric truck is most effective were discussed, the speaker admitting that, beyond a certain range, the electric vehicle could not compete with the oil-driven machine. He concluded his address with descriptions of some of the motors used on electric vehicles, which motors ranged from 70 to 90 lb. h.p. and had a great overload capacity, a maximum efficiency of between 85 and 90 per cent and a long range of high efficiency.

NECROLOGY

WILLIAM ALEXANDER CHERRY, JR.

William Alexander Cherry, Jr., was born in Denver, Colorado, in October, 1888, and was graduated from Columbia University in 1911. During the summer of 1909 he served a machine shop apprenticeship with the Acme Machine Company of New York and a power plant apprenticeship with the New Rochelle Light and Power Company of New Rochelle during the summer of 1910. After his graduation from Columbia he became associated with Viele, Blackwell and Buck, of New York, Consulting Engineers. While with them he worked on several designs such as hydraulic power stations and machines for a new Gas Producer. He was also employed in the laboratory on the practical end of the above process in testing out various materials to be used in the manufacture of producer gas.

For the past two years Mr. Cherry has been connected with the Florida Abstract and Title Insurance Company of Jacksonville, Florida. He died in Atlanta, Ga., on March 6.

HENRY G. MORRIS

Henry G. Morris was born in Philadelphia May 25, 1839 and graduated from Haverford College. He engaged in active manufacturing business in early life, and when still a very young man was a member of the celebrated firm of Morris, Tasker & Co., who were the first manufacturers of wrought iron pipes and boiler flues. A few years later he became the sole owner of the Southwark Foundry, where some of the largest blowing engines, pumps and other heavy machinery were constructed, and at that time was justly regarded as one of Philadelphia's greatest captains of industry. Mr. Morris was one of the first Directors of the Pennsylvania Steel Company, and was one of the few men in this country, like Alexander Lyman Holley, to recognize the importance and value of the Bessemer process. He was a leader in the design and manufacture of the most diversified kinds of machinery used on sugar plantations and in refineries, gas plants and water works, and among the first in this country to recognize the value of compound engines in marine engineering.

He early became interested in electrical engineering, and will undoubtedly be best remembered in connection with Mr. Salom in the invention and development of the Electric Vehicle for which, twenty years ago, they received the gold medal of the "Times-Herald" Motorcycle contest in Chicago, 1895 (the birth of the automobile), and the John Scott Legacy Medal of the Franklin Institute, Philadelphia. He took out numerous patents in connection with the same and for storage batteries.

He was a member of many national societies and associations, including the American Society of Mechanical Engineers, of which he was a past vice-president; The Engineers

Club of Philadelphia, of which he was a past president; The American Institute of Mining Engineers, The American Society of Civil Engineers, The Franklin Institute of Philadelphia, and the Union League of Philadelphia, of which he was the oldest living member in point of time with a single exception. He was elected a member February 14, 1863. Mr. Morris died on January 19.

FREDERICK WINSLOW TAYLOR

Frederick Winslow Taylor, Past-President of The American Society of Mechanical Engineers, died in Philadelphia on March 21. He was born in Germantown, Philadelphia, in 1856. His primary education was obtained in this country and in France and Germany. By night study he secured the degree of Mechanical Engineer from Stevens Institute of Technology.

He served apprenticeships in pattern making and at the machinist's trade in Philadelphia, and began practical work in the shops of the Midvale Steel Company in Philadelphia, where in six years he worked up to the position of chief engineer. Beginning here and continuing later at the works of the Bethlehem Steel Company, he made a scientific study of labor problems and efficiency and put into operation principles of scientific management which have since received world wide attention and application in many industrial organizations. Incidentally, this work led to the study extending over a period of 26 years of the laws of cutting metals; and the development of the Taylor-White process for the heat treatment of steel for cutting tools.

A more complete account of his life, with appreciations of his career, appear in another part of this issue of The Journal.

PERSONALS

Louis M. Zach has become associated with the engineering department of the Anaconda Copper Co., Anaconda, Mont. He was until recently mechanical engineer with the Doe Run Lead Co., Rivermines, Mo.

Thomas A. Bennett, who for the past five years has had charge of the conveyor and elevator belt sales of the B. F. Goodrich Co., Akron, O., has severed his connection with that company and has become the assistant to the general sales manager of the New Jersey Zinc Co., with offices in New York City.

Stephen G. Luther is now connected with the alkali division of the Philadelphia Rubber Works Co., in Akron, O., as manager of the experimental department. He was formerly located at the Philadelphia factory of the company.

J. E. Woodwell announces the dissolution of his partnership with L. B. Marks and will locate at 8 W. 40th St. about May 1, where he will continue the general practice of consulting engineering.

Clarence M. Davison has resigned his position as assistant chief engineer of the Kennedy Stroh Corporation, Oakmont, Pa., and has accepted the position of general manager of the Westbrook Elevator Company, Danville, Va.

Louis T. Sieka has resigned his position as mechanical superintendent of the Tooele Plant of the International Smelting Company, Tooele, Utah, and has accepted the position of mechanical superintendent and engineer for the St. Joseph Lead Co., Bonne Terre, Mo.

Wm. F. Gillies has become manager of the Ingersoll-Rand Co., Pittsburgh, Pa. He was until recently New York branch manager of the A. S. Cameron Steam Pump Co.

Joseph L. Gilson has severed his connections with the De La Vergne Machine Co. of New York, and has accepted a position with the Arctic Ice Machine Co., Canton, O.

Henry R. Towne has retired as president of the Yale & Towne Manufacturing Company, a position which he held for 46 years, and has been elected chairman of the board of directors. To fill the vacancy created by Mr. Towne's partial retirement from the activities of the company, the directors have elected as president, Walter C. Allen, until recently vice-president and general manager of the company.

Frederick Ray has recently opened an office at 50 Church St., New York, as Consulting Engineer, where he will make a specialty of centrifugal pumping machinery, condensing equipment, cooling towers and similar apparatus.

Charles H. Schmalz is manager of the Billings Foundry and Manufacturing Co., Billings, Mont. He was formerly associated with the Boston and Montana Reduction Department of the Anaconda Copper Mining Co., Great Falls, Mont., as assistant master mechanic.

STUDENT BRANCHES

ARMOUR INSTITUTE OF TECHNOLOGY

A meeting of the Student Branch of Armour Institute of Technology was held on March 11 at which the following officers were elected: G. F. Gebhardt, honorary chairman; J. M. Byanskas, president; B. S. Carr, vice-president; E. S. Echlin, secretary; L. Luckow, treasurer.

G. F. Wetzel, '12, read a paper on paints used on engineering work. The paper contained a description of the constituents of the paints used on structural work and similar engineering work. Formerly it was taken for granted that any kind of paint would do, but now large buyers test paint submitted before purchasing. In government work, the paint has to conform to the standard formulae worked out in the testing department.

BROOKLYN POLYTECHNIC INSTITUTE

The Polytechnic Institute of Brooklyn Student Section held its regular monthly meeting on March 6, at which Dr. Magnus C. Hilseng, consulting professor of Works Engineering at the Polytechnic Institute, gave an illustrated talk on Coal Mining. The speaker outlined the methods pursued in mining, the ventilation safety methods and the costs of the different grades of coal.

V. N. Hewlett, a student, read a paper on Modern High Speed Automobile Motors, showing the progress made since 1907 in automobile motor design, with special reference to the different types of valves which have been perfected.

Since January 15, excursions have been made to the following places of interest: January 16, Hecker-Jones-Jewell Milling Company, New York City; February 20, Nicholas Power Company, manufacturers of moving picture machines, New York City; February 27, Morse Drydock and Repair Company, South Brooklyn; March 6, Power Station of the New York Central Railroad at Port Morris.

During the spring vacation of the Institute, an inspection trip will be undertaken by members of the Branch, including the cities of Cleveland, Detroit, Chicago, Cincinnati and Pittsburgh.

At this meeting the resignation of the secretary of the Branch, Samuel Kohre, was accepted and George A. Wieber was elected to take his place for the remainder of the present year.

CARNEGIE INSTITUTE OF TECHNOLOGY

The regular meeting of the Carnegie Student Branch of The Am. Soc. M. E. was held at Machinery Hall on February 10. W. C. Stevenson, C.E.T. '08, read a paper on The Mechanical Engineering Involved in Erecting an Electrically Driven Bar Mill, at the Duquesne Works of the Carnegie Steel Company. He gave a detailed account of many of the problems which had been solved in the erection of this mill,

and described its peculiar features. For instance, the rolling of the bar is entirely automatic, no catchers being used. Mr. Stevenson illustrated his talk with the blue prints which had been used in the construction of the mill. The paper was discussed by Professor Trinks.

COLORADO AGRICULTURAL COLLEGE

At a meeting of Colorado Agricultural College Student Branch on February 17, the article by F. R. Low in the October issue of *The Journal on Pulverized Coal for Steam Making*, was reviewed by T. H. Sackett. His talk brought out the economical use of pulverized coal as compared with lump coal. This was followed by a general discussion.

Mr. Murray gave an interesting talk on Safe Steel Rails, and placed emphasis on the numerous tests made to determine flaws and the method of eliminating them.

At a meeting on February 26, Large Steam Power Plants was the subject of an instructive talk by Mr. G. G. Law. His subject covered the work in the whole plant, but more especially the boiler room and the new appliances used there. At the close of the paper Mr. Law answered several questions on his subject.

Mr. Morrison discussed the paper on Industrial Service in Engineering Schools by J. W. Roe, which appeared in the June issue of *The Journal*. He gave a history of the work and then spoke of the problem of Americanizing the laboring immigrant. Professor Crain spoke briefly on the same subject, comparing the ordinary reform methods with those in the line of industrial reforms. He brought out clearly the practical side of the subject and showed how the men could help to solve the problems of capital and labor. Mr. Stephens discussed briefly the subject of Industrial Service Work which he himself had seen in Chicago.

KANSAS STATE AGRICULTURAL COLLEGE

At a meeting of the Kansas State Agricultural College Student Branch on February 4, E. Lee Heidenreich, a consulting engineer of Kansas City, Mo., addressed the Branch on Reinforced Concrete in some Engineering Branches. Mr. Heidenreich gave a short history of the use of concrete, especially the Monier construction or, as it is now known, reinforced concrete. The speaker advocated a more extensive use of concrete in all types of construction, its greatest value being that it is almost fire and water proof. Mr. Heidenreich discussed the use of reinforcing and some of the advantages and disadvantages of the forms now in use. He personally preferred steel of high elastic limit from 50,000 to 55,000 lb. per sq. in., avoiding twisted square bars and using bars with the deformations at right angles to the axis of the bar.

On March 4, H. R. Setz, a member of The Society and Chief Engineer of the Fulton Iron Works, St. Louis, gave an illustrated lecture on the Development of the Diesel Engine. Mr. Setz has had experience in Europe with the earlier types of Diesel Engines. He very clearly pointed out defects in the first non-jacketed types and also the impracticability of using the same valve for controlling the inlet and exhaust events. By means of original diagrams he illustrated the difference in temperature between the actual Diesel diagram and the ideal Diesel engine.

KANSAS UNIVERSITY

The regular weekly meeting of the Kansas University Student Branch was held on February 25, at the home of Dean P. F. Walker. Floyd Nutting gave a description of the water-power development at Keokuk, Iowa. Mr. Nutting visited this plant in November 1914, and spoke chiefly from notes taken at that time. After describing the dam and power house equipment, he spoke of the service and transmission lines with particular reference to the power furnished the city of St. Louis. He also gave some ideas of the size and construction of the government locks at the Keokuk dam.

B. O. Bower spoke on the Kansas City Automobile Show, which was held February 8 to 14, 1915. He told of the tendencies in design which 1915 cars are following, and com-

pared in some detail the motor part proportions of the new cars with those of earlier models and explained the reasons for the changes.

LELAND STANFORD UNIVERSITY

At a meeting of the Leland Stanford Mechanical Engineering Association on February 9, the resignation of H. M. Henderson as secretary of the Branch was accepted, and C. L. Addleman was elected to fill the vacancy.

Prof. W. F. Durand addressed the society on ways of making the meetings for the present semester a success. An illustrated talk on Automobile Foundry Work was given by B. M. Green, President of the Branch. The speaker laid emphasis on the arrangement of molds and conveyors in the modern shop. The slides showed the Ford foundry and a large jobbing foundry.

MASSACHUSETTS INSTITUTE OF TECHNOLOGY

On February 24, at a meeting of the Massachusetts Institute of Technology Student Branch, Mr. Gillespie of the United Shoe Machinery Company of Beverly, Mass., gave a very interesting talk, illustrated by moving pictures, on From Pelt to Welt, in which he took up the complete process of making Goodyear welt shoes. Mr. Gillespie gave the history of the shoe as one of the garments of man and traced its development from 4000 B.C. to the present time. He showed pictures of many of the old types of shoes, and compared some of the very earliest shoes with the shoes now worn by the Mexican army, showing the close resemblance. The speaker also told of the development of the royalty system used by the United Shoe Machinery Company today, and showed pictures of some of the company's welfare work.

OHIO STATE UNIVERSITY

On February 27, Calvin W. Rice, Secretary of The Society, addressed the members of the Ohio State University Student Branch on the 1913 Trip of the Am. Soc. M. E. to Germany. Before touching this subject, however, Mr. Rice spoke briefly of The Engineering Foundation, the coming meetings of the Society, The International Engineering Congress, and The Pan American Congress to be held in Washington. The excellent library facilities which the Society offers to its members were mentioned, also the purpose and object of the Student Branches was reviewed.

In speaking of the future of the engineering profession, Mr. Rice stated that it was certain to supplant the influence of the lawyers and doctors as leaders of men; and that the future engineer would cease to deal with things entirely and would deal more and more with men and would thereby become more prominent in politics and in the progress of established communities. Mr. Rice pointed out the extreme difficulty the United States was having and would have in maintaining her neutrality, and advocated the establishment of a civilian engineering reserve corps to assist the work of the war department in the defense of our coast cities.

The talk on the 1913 trip of the Society to Germany was illustrated by numerous excellent lantern slides, which impressed one with the wonderful organization of the German nation, the sincere and genuine hospitality which it extended to the American visitors and also with the high public esteem which the engineering profession there enjoys.

PENNSYLVANIA STATE COLLEGE

The new officers of the Pennsylvania Student Branch were installed at a meeting on February 12. William Blume read a paper on the Diesel Engine, giving an interesting and detailed account of the construction, operation and characteristics of the Diesel Engine together with a biographical sketch of Rudolf Diesel.

On March 4, there was a special literary meeting. A paper on the Keeler Boiler was read and illustrated with stereopticon slides which were furnished by the Eugene Keeler Company.

PURDUE UNIVERSITY

At a meeting of the Student Branch of Purdue University on February 9, the following officers were elected for the

second semester: B. J. Davidson, chairman; R. T. Gray, vice-chairman; O. F. Hambrook, recording secretary; V. P. Craig, corresponding secretary; J. M. Lonn, treasurer. J. W. Trimmer, '15, gave an illustrated lecture on Air Brakes.

At a meeting of this Branch on February 23, E. G. Stradling, signal engineer with the Monon Railroad, gave a paper on Signal Engineering and Apparatus. He said that the art of signaling as applied to steam and electric railways is divided into two general classes. These are known as interlocking signaling and block signaling. As the word implies, the term interlocking when applied to signaling means that certain switches and signals are so inter-connected with one another, that they must be operated in a pre-determined sequence. Interlocking is used for the protection of trains in their movements at railroad crossings at junction points and at points where there are several switches used by a large passenger terminal. The well known term of block signaling means that a railroad between certain points is divided into short sections of a desired length, each section known as a block and the entrance of a train into each block is regulated by a signal of some design.

Today for a simple crossing of two single tracks, we have on each track approaching the crossing a derailed located in most cases five hundred feet from the crossing. Fifty-five feet beyond this is located the home or positive stop signal and farther out some three or four thousand feet is located the distant or caution signal. All of the derails with their locks and all of the signals are controlled by levers grouped together in a tower near the crossing. These levers are controlled by one man and are all normally placed in the position which has all derails set against traffic and all signals set so as to stop all trains. The levers which control these respective functions of the plant are so connected mechanically that not any one of the caution signals can be moved to the proceed indication for a train until its respective home signal has first been moved to the proceed position. Neither can the home signal give the proceed indication until both the derails on that track have been set and locked for the passage of the trains, and with the first movement of the levers that set the derails for a passage of the train on that track, the derail levers for the other track are locked in their normal position so that neither they nor the signal on that track can be moved but must remain in a position to oppose traffic. From this simple plant with its twelve or fourteen levers, one can go to the plant in some of the new passenger terminals, one of which has over four hundred levers.

Block signaling as defined by the Inter-state Commerce Commission consists of a scheme for maintaining a space interval between trains as distinguished from the train rule system of attempting to maintain a time interval. This can be accomplished either by a manual block system or an automatic block system. The manual block system which was first introduced on the American railways in about the year 1863, requires the coöperation of two men for each block, generally telegraph operators, one of whom notifies the other when a train enters the block while the second notifies the first as soon as the train has passed out, so that the first operator may permit a second train to enter.

In the year 1879, the track circuit was introduced and thus began the development of the automatic block signal system. The track circuit consists of a source of electric energy, usually a primary battery connected one pole to each of the two rails of the track, using the rails as conductors and of a relay connected between the rails at the outer end of the circuit. The presence of a train on the rails will shut the circuit and open the relay, likewise any interruption to the circuit from a broken rail or open switch will cause the relay to open. By the control of the secondary circuit through this relay, it is possible to operate the block signals in any manner that may be desired.

STEVENS INSTITUTE OF TECHNOLOGY

On Wednesday, February 17, the Student Branch of The Am. Soc. M. E. of Stevens Institute of Technology conducted an inspection trip to the Crucible Steel Company, in Harrison, N. J. The party was made up of about twenty students

who were guided through the plant and shown the three processes employed by the company in the manufacture of chrome, nickel and tungsten steels: the open hearth, the electric furnace and the crucible methods.

The following Wednesday, the Stevens Engineering Society visited the Kenfelf and Esser factory in Hoboken to see the manufacture of drafting and surveying instruments. The trip through the plant was very instructive, but the party was prohibited from inspecting the secret processes, such as the graduation of the Kenfelf and Esser slide-rule. The periscope which was being constructed in the factory at the time of the trip was of particular interest because of the recent German submarine raids on the English coast.

On Friday of the same week, Charles H. Day of the Aircraft Company, at Bound Brook, N. J., gave a further insight into machines of war, by a lecture on the Engineering Principles of Aeronautics. Mr. Day, who has had much experience in the building and flying of aeroplanes, was in an advantageous position to talk from the birdman's point of view. The most remarkable of his statements was that about nine out of every ten flying machines built in the United States have been built without a stress diagram.

UNIVERSITY OF CALIFORNIA

At a meeting of the Student Branch of the University of California, A. C. Moorhead gave a paper on State Liability and Compensation Insurance. The paper was discussed by Prof. R. S. Tour, Rene Guillon, H. L. McLean and Robert Christy.

H. L. McLean read a paper on Valuation of Public Utilities. It was discussed by Professor Tour, Rene Guillon, Charles Ball, A. C. Moorhead and Robert Christy.

UNIVERSITY OF CINCINNATI

There was a meeting of the University of Cincinnati Student Branch on February 24. The speaker of the evening, Prof. C. A. Joerger of the Mechanical Engineering Department, gave a paper on Present Day Problems and Tendencies. Professor Joerger called attention to the modern tendency to consider all men equal. The speaker held that this is a false ideal, and that men, rich and poor alike, should be judged by their inherent worth. Respect should be equal, but not the reward. It was pointed out that the tendency is to suppress individual initiative, and that this results in placing incompetent men in positions of responsibility. As corollary to the foregoing tendency, the speaker further emphasized the inclination to disregard experience and authority. His paper was received with great interest, and his conclusions met with general approval.

On February 25, Calvin W. Rice, Secretary of the Society, spoke to the student body on The Advantages of Membership in the Student Branch of the Society. Mr. Rice pointed out that the Society is of great help to engineering students, whether in the mechanical, electrical or civil department. He showed that through The Journal, the Society was furnishing at cost to the students a large body of data on all phases of engineering and was giving them the benefit gratuitously of research work carried on by the special staff of The Am. Soc. M. E.

Mr. Rice gave a lecture illustrated by stereopticon views on the visit of a delegation of the Society to the engineers of Germany. The German Government had one of their best engineers visit this country in advance of the date upon which the American delegation was to sail. This engineer after his return to Germany devoted his time and energy to preparation for the entertainment of the visitors. As a result, all arrangements for traveling, lodging, and sight seeing had been worked out to the smallest detail, and though all the principal cities and engineering works were visited, there was no hitch in the program and there were none of the numerous petty annoyances to which travelers are usually subjected. In every city, the visitors were received with great courtesy by the Mayor (always an engineer) and in many instances they were entertained by the highest officials. Everywhere the delegation was impressed with the remarkable efficiency of the German industrial organization.

UNIVERSITY OF COLORADO

At the meeting of the Colorado Branch on February 25, a paper on Mechanics of Mining was presented by Frank E. Shepard of the Denver Engineering Works. He dealt with the process of mining from the mine to the smelter, taking up the machinery used and its development. With his experiences in the manufacture of mining machinery, he gave descriptions of the various types used for the different purposes. He said that an electric drill which used 14 h.p. had lately been developed, but that type of drive had not made the progress it should have made owing to the class of men called upon to handle it. The speaker showed that hoisting machinery is not a simple arrangement because of various attachments and combinations which introduce many complicated problems. The many ways of solving these questions were shown by means of sketches on the blackboard and were extremely interesting. The ore must be crushed in all sizes to free it from the gangue and make the mineral obtainable in a very finely powdered state. This crushing must be done in stages and many different kinds of crushers are in use. After crushing, the cyanide process is used to leach out many of the values. In some cases, the slime flotation method and in others the various types of concentration tables are used. The cooperation of all the branches of engineering are needed, thus requiring many men in one company to produce the results. Mr. Shepard further emphasized the importance of not discarding apparatus and machinery without a thorough trial under working conditions.

On March 11, Charles Hall of the Mine and Smelter Company, Denver, gave a short but interesting talk on Centrifugal and Triplex Pumps. He went into the conditions and arrangement of pumping machinery on different jobs, and mentioned the data needed in order to figure on various cases. Centrifugal pumps will carry about 30 per cent overload.

UNIVERSITY OF KANSAS

A feature with the Student Section of the University of Kansas which is unique among all the student sections of The American Society of Mechanical Engineers is the plan of holding an annual meeting with morning and afternoon sessions, a dinner and speech making in the evening.

The sixth annual meeting was held on February 18 and was largely attended. A series of meritorious papers was presented, several of which it is hoped to publish in abstract in future numbers of The Journal. The morning and afternoon sessions were unusually interesting and contained papers as listed below. In the evening 125 attended the banquet. The papers presented were as follows:

THE RELATION OF TECHNICALLY TRAINED MEN TO THE INDUSTRIES, by Walter Rautenstrauch, professor of mechanical engineering at Columbia University, New York. This paper considered in detail some of the fields of service for the engineer and indicated what practice in these fields involved.

INTERNAL COMBUSTION MOTORS, especially the oil engine type, with special reference to the pumping service in the oil fields, by S. A. Salentief, chief engineer of the Prairie Pipe Line Co., Independence, Kan.

RATE MAKING IN PUBLIC UTILITIES, by Geo. C. Shaad. This paper dealt with the different types of service charges, including a consideration of intangible values and readiness-to-serve as elements in the problem.

SOME PHASES OF CEMENT MANUFACTURING, by C. A. Swiggert, assistant superintendent of the Iola Portland Cement Co.

MANUFACTURE OF GASOLINE FROM NATURAL GAS, by Louis Bendit, consulting engineer, Kansas City, Mo.

HEATING AND VENTILATING APPARATUS, by H. B. Kraft, of the Kansas City branch of the American Radiator Co.

THE RESULTS OF ORIFICE TESTS CONDUCTED AT JOPLIN, MO., by Ernest O. Hickstein, engineer with the Wichita Natural Gas Co. This investigation dealt very fully with the conditions of air flowing through orifices and was an important investigation in the field of gas engineering. In conducting these tests, a gas holder of 250,000 cu. ft. capacity was used.

SERVICE EQUIPMENT OF THE HARRIS TRUST BUILDING IN CHICAGO, by I. W. Clark, student member.

ENGINEERING PROBLEMS ARISING IN THE TRANSPORTATION OF NATURAL GAS, by Jas. P. Fisher, chief engineer of the Wichita Natural Gas Co.

Prof. Walter Rautenstrauch of Columbia University, New York, who presented one of the papers, has kindly sent the following communication giving his impressions of this meeting:

"It was my pleasure to be the guest of the Student Branch of the A.S.M.E. of the University of Kansas at its Sixth Annual Meeting held Thursday, February 18, 1915, at Lawrence, Kansas. I was so favorably impressed with the work of this branch of the Society that I feel it would be well for each member of the Society to know how excellent a meeting of this sort may be. I, therefore, beg to submit to you an account of this meeting for publication in The Journal. The program which I enclose herewith contains a series of papers representing broad fields of activity of Mechanical Engineering and each one was presented in an interesting and instructive manner. The last two papers on the Flow of Air Through Orifices, by Mr. E. O. Hickstein, and Engineering Problems in the Transportation of Natural Gases, by Mr. James P. Fisher, were of a standard commensurate with those presented to the Society at its annual meetings. The students showed a real interest in each one of the papers presented and the whole meeting seemed to create a very deep impression on the minds of the students. The evening was devoted to a banquet at the principal hotel in Lawrence, at which about 125 members were present. A number of addresses were made at this banquet and a very pleasant evening was had by all those present. Great credit is due to Dean P. F. Walker for the manner in which he has conducted these annual meetings and it is believed that the work of this student branch may well be a model to all student branches throughout the country. It has occurred to me in this connection that a great benefit would result if there should be appointed a set day in the year to be known as the annual meetings of student sections of the A.S.M.E., at which time the whole day should be turned over to the presentation of papers such as is being done at the University of Kansas. It is felt that a definiteness would be given to the purpose of this work which would result in considerable benefit to the Society."

UNIVERSITY OF KENTUCKY

A meeting of the Student Branch of the University of Kentucky was held February 18. P. L. Kaufman of the class of 1901, who is at present employed by the Bascule Bridge Company, gave an interesting talk demonstrated with numerous drawings on the principle and construction of the bascule-bridge. He also devoted a part of his time to a discussion of the aeroscope at the Panama Pacific Exposition. This instrument was invented by Mr. Strauss and a detailed discussion of it has lately appeared in Engineering News.

UNIVERSITY OF MINNESOTA

A special meeting of the Minnesota Branch of the Society was held on February 25. Prof. S. C. Shipley of the Mechanical Engineering Department, University of Minnesota, gave a talk on Automobile Ignition Systems. He described first the early attempts at ignition by other means than the electric spark, and then the various modern ignition systems. The talk was illustrated by lantern slides. Because of the general interest of the subject to all engineers, the meeting was thrown open to all who cared to attend. There were forty-six people present.

In the Experimental Building on February 27, the Branch held a Get-together for all mechanical engineering students of the college and their friends. Prof. W. H. Kavanaugh, head of the Experimental Engineering Department, spoke of the history and achievements of the Am. Soc. M. E. Prof. J. V. Martenis, acting head of the Mechanical Engineering Department, gave an interesting description of a perpetual motion machine, about which his advice had been asked. J.

F. Colvin spoke of the purposes and aims of the Student Branch.

An open meeting of the Minnesota Branch was held March 4, in the Auditorium of the Main Engineering Building. Mr. Jackson of the Niagara Falls Carborundum Company gave a stereopticon lecture on the method and process of carborundum manufacture at the plant with which he is connected. He described in detail the power plant, the various departments of the manufacturing plant and their functions, and some of the many and varied uses to which carborundum products are put. The lecture was well attended.

UNIVERSITY OF MISSOURI

At a meeting of the University of Missouri Student Branch on February 18, I. O. Royse gave an interesting and scientific lecture on the gyroscope. He commenced with the history of the gyroscope, its first users and early applications. He then explained the general laws of the gyroscope as they were formulated by Foucault, and how they were made use of by Schlick and Brennan. With the aid of lantern slides, he showed many present day applications, for example, mono-rail cars, gyro-compasses, two wheeled automobiles and stabilizers for ships. The gyroscope forms the essential parts of the steering apparatus of torpedoes. He also discussed the gyroscopic effect of the fly wheels of motor cars and aeroplanes.

At a meeting on March 4, Mr. F. A. Heileman gave a talk on the Heating System of the University. He first explained heating systems in general, including everything from a fire place to the modern steam system, and showed how the various principles were made use of in the local institution. Some of the many automatic devices for regulating the steam pressure, eliminating the air and removing water from the heating systems were described, together with the consequences of ignorant or careless handling.

WASHINGTON UNIVERSITY

The Student Branch at Washington University has been fortunate throughout the present school year in having heard lectures on a variety of engineering subjects by men who are known, some of them perhaps only locally and some far and wide among engineers.

Among the speakers were Earl B. Morgan, Safety Engineer for the Commonwealth Steel Company, who gave an illustrated talk on The Safety Movement in the Industry and its Relation to the Engineer.

H. R. Setz, Chief Engineer Oil Engine Dept. Fulton Iron Works, St. Louis, Mo., delivered an illustrated lecture on Some Phases in the Development of the Diesel Engine. He had drawings of Diesel's first experimental engines and gave a complete account of the early history of the engine, explaining the difficulties experienced in trying to make the Diesel cycle practicable.

Dr. M. Von Reehlinghausen whose system of water purification is much in use, even in the present European War, lectured before the Society on Ultra Violet Rays and their Application to Water Purification.

Dr. Thomas Watson, who assisted Graham Bell when he invented the telephone, gave a most interesting talk on his association with Graham Bell and the telephone.

WORCESTER POLYTECHNIC INSTITUTE

The Worcester Polytechnic Institute Branch held on February 19, a joint meeting with the Civil and Electrical Societies, to welcome home George H. Throop of the class of 1897, who addressed them on the subject of Public Utility Appraisals. Mr. Throop has been for some time with the J. G. White Company of New York City and was recently connected with the appraisal of the Pacific Gas and Electric Company's property, an immense system in California covering 40,000 square miles of territory. The speaker was in charge of the electric and street railway part of the work. His exposition of the various methods of figuring depreciation of plant and accessories was of particular interest to the seniors in the Mechanical Engineering course on account

of the work in Shop Management. The lecture was illustrated with slides which showed the nature of the country, the power plants and transmission lines.

On March 5, there was an open meeting of the Branch. Invitations were extended to the members of the Worcester Automobile Club and their friends as well as to the general public. W. H. Weingar, representing the Maxwell Automobile Company, gave an interesting lecture on From Molten Metal to the Finished Automobile. The lecture was illustrated by several motion picture films, showing views of the factory and some outside points of interest.

EMPLOYMENT BULLETIN

Note: In sending applications stamps should be enclosed for forwarding.

The Secretary considers it a special obligation and pleasant duty to be the medium of securing positions for members, and is pleased to receive requests both for positions and for men. The published notices of "men available" are made up from members of the Society. Notices are not repeated except upon special request. Names and records are kept on the office list three months, and if desired must be renewed at the end of such period. Copy for the Bulletin must be in hand before the 15th of the month.

POSITIONS AVAILABLE

057. Company selling engineering specialties wishes services of technical man familiar with power transmission machinery and having \$5000 to invest. Apply through Society.

059. Mechanical engineer and chief draftsman in the engineering department of a large industrial concern. Prefer man who has had several years experience in design of coal and ore handling apparatus and its application, ore and slag crushers, blast and zinc furnaces; steel, brick and wood buildings, bridge work and general steam and power plant engineering. Name confidential, apply by letter.

068. Man capable of taking charge of tool department in manufacture of sterling silver hollow ware; one who understands generally, machine shop practice, but more particularly familiar with up-to-date methods of working sheet metal, such as rolling, cupping, drawing and spinning; have charge of laying out the tools to manufacture the goods and supervise the making of the tools and their operation. Any knowledge of up-to-date methods of shop practice of advantage. Position has good future for the right man. Salary will depend entirely upon what experience the man has had in this or a similar line. Location New England.

069. Steam specialty salesman who desires to take on a line of vacuum heating specialties. Representatives wanted in all the leading cities. Apply through Society.

070. High class designer on automatic machinery wanted for concern in South.

071. Competent machine tool designer with manufacturing experience in the design and maintenance of machine tool equipment of factory, manufacturing work in large quantities, on interchangeability of part system. Desires man to take charge of drafting force; essential that he have ample machine shop experience and be familiar with jigs, fixtures, turret and automatic screw machines, machines, etc. Location New York State. Apply through Society.

072. Young man, aggressive and possessed of initiative, wanted as assistant professor of electrical engineering. Must be first of all a teacher, but have had some practical experience. Location, New England. Apply through Society.

078. Position as works manager, government dock yard at Newcastle, Australia. Salary 750 pounds sterling, three years engagement. Exceptional opportunity. First-class rail and steamer transportation allowed. Apply through Society.

079. Factory manager for plant located in Cleveland, making parts for automobiles and employing normally six hundred men. Applicant must have experience in heavy and

light manufacturing machinery for automatic production, heat treating methods of metals, efficiency methods as to production and cost, and must be capable of handling men. State age, references and salary desired, or present salary. Apply through Society.

080 Opportunity desired for investment by man interested in engineering projects, who wishes to be associated in an established, "going concern" in construction or manufacturing enterprise where financial assistance would assure a managerial position. In position to secure investment interests of other parties. Name confidential. Apply through Society.

082 General superintendent to take full charge of works manufacturing cartridges. Name confidential. Apply through Society.

MEN AVAILABLE

D-41 Technical executive, mechanical engineer, young man, experienced in design and construction of special machinery, maintenance of property and engineering, construction and operation of power plants and buildings, high voltage transmission, etc. Past five years superintendent of plant department employing 225 men, desires to make change, with better opportunities. Present salary \$4000 per year.

D-42 Associate member, M.I.T. graduate, age 27, five years experience teaching, in factory and laboratory, desires to work through each department of factory with object of becoming assistant superintendent.

D-43 Graduate mechanical engineer, age 27, has worked as apprentice, in machine shop, draftsman, estimator and outside trouble man for large manufacturing concern, also efficiency man in food producing concern, desires position combining inside and outside work or as testing engineer.

D-44 Junior member, graduate mechanical engineer with post graduate course in hydraulic and water power engineering at M.I.T., employed for the past year in the State of Washington on hydrographic survey and river improvement work, desires position with company in hydraulic construction work. Location preferred western states.

D-45 Member, graduate mechanical engineer, University of Pennsylvania, eleven years experience in design and erection of hydraulic riveters and presses, steam hammers, steel mill machinery and elevator safeties, desires position as engineer or chief draftsman.

D-46 Member, expert on machine shop practice and modern tools, successful experience as superintendent of large shop, and sales manager of well known machine builders, would like to represent responsible concern in New York or Philadelphia. Salary or salary and commission.

D-47 Junior, age 26, unmarried, two years experience in cost and efficiency work, capable of producing results, desires position with firm contemplating installing efficiency methods for cost systems.

D-48 Member, graduate mechanical engineer, 20 years experience as designer and chief draftsman with leading manufacturers of simplex and duplex steam pumps, desires position.

D-49 Junior, technical graduate, experienced in hydraulics, steam, gas and oil engineering, three years in the tropics, sales work, general mechanical installation and operation, desires permanent connection with reliable firm.

D-50 Member, A.S.M.E. and S.A.E., age 37, thorough practical experience designing manufactured articles, laying out plants, designing and building special equipment and tools, inaugurating economical production and clerical systems, producing results, desires position offering a wider field than possible with present employers.

D-51 Junior, graduate M.E., who will very shortly complete a special apprenticeship with one of the largest rail-

road systems, desires position where this training will be of immediate value. Location immaterial.

D-52 Member, age 32, married, 15 years practical and executive experience in machine tool, automobile and gear manufacturing with representative concerns, now employed as superintendent, desires position along similar lines, or would take an interest in small firm having meritorious line to manufacture. Replies treated confidentially.

D-53 Junior, graduate M.E., four years experience in manufacturing and designing, desires similar position on local commercial line. At present in assistant executive position.

D-54 Junior, technical graduate in mechanical and electrical engineering, 12 years varied experience in design, construction, operation and maintenance of power houses and sub-stations; familiar with up-to-date methods of mapping and execution of construction and repair orders in power plant and mill accessories, experienced in testing and experimental work, possessing executive ability and pleasing personality, desires position of power engineer, assistant superintendent, assistant manager or works manager. At present employed. Location preferred, New York or vicinity.

D-55 Student member, age 23, graduating in June 1915 from Stevens Institute of Technology, experienced as draftsman, mechanic's helper on erection work, inspector of gas and water supplies, automobile repairs, and general office work in connection with railway association, desires any position which offers opportunity for advancement.

D-56 Engineer, with broad designing experience on metal working machinery and tools, is open for position. Can offer an improved design of machine in several sizes for a company wishing to extend their line. Location, middle West preferred.

D-57 Member, technical graduate, wide training and experience in design of power plants and machinery, construction, maintenance and operation, purchasing engineering material, executive charge of all consulting engineering work, including building construction of all kinds, desires position as works manager or superintendent.

D-58 Junior member, age 28, graduate mechanical engineer, five years practical experience, last two and one half years engineer of tests of large automobile company, desires position as assistant superintendent or engineer.

D-59 Mechanical engineer, Lehigh graduate 1912, three years experience in maintenance and equipment work, desires position. At present employed.

D-60 Member, age 35, technical graduate, married, 12 years experience in design, operation and construction of steam electric plants and purchasing equipment; specialist in fuel economy and fuels, desires position as mechanical or power plant efficiency engineer with company operating steam plant or chain of plants of large capacity in which better operating economy is desired. At present employed, but seeks position with chance for advancement.

D-61 Junior member, age 29, mechanical and electrical engineer, 12 years experience in design, construction, operation and maintenance of power plants of public utility and industrial corporations, having held positions as superintendent and chief engineer, and in charge of complete power tests, desires position with consulting engineer or large engineering corporation, or as power engineer for industrial corporation. Location immaterial.

D-62 Member, at present employed, but desiring greater opportunity, would consider position in engineering or designing department of concern requiring the services of a practical man with experience in elevator work. Location preferred, Eastern states.

D-63 Member with wide practical experience, fully acquainted with machine tool market, domestic and foreign,

travelled here and abroad, would like to represent first class firm in eastern territory; will travel if necessary. At present holding position as sales manager.

D-64 Member, engineering graduate, 14 years practical experience, four years as instructor in mechanical engineering, would consider position in well known engineering school or college. At present employed.

D-65 Associate-member, engineering graduate, six years teaching and four years general engineering experience, desires position for the coming academic year in mechanical department of a technical school.

D-66 Member, age 36, graduate M. E. of M. I. T., whose present position and previous work has required initiative, executive ability, tact, organization of men and the direction of their efforts along business lines as well as engineering. Experience also includes buying, selling, manufacture and construction work; familiar with office management, costs, keeping proper records and handling correspondence.

D-67 Associate member engaged at present in engineering sales line desires position as salesman or assistant sales manager.

D-68 Member, also Member Institution of Mechanical Engineers, for 16 years with exporters and importers of machinery, in charge of technical department in London and Tokyo, with wide experience in all technical and commercial work and in the American, European and Japanese markets; English, German, French correspondence, also some Spanish, requires responsible situation in similar capacity.

D-69 Junior, post-graduate M. E., Purdue University, age 31, nine years engineering experience in industrial management, has served successfully as special machine shop and foundry apprentice, staff engineer with production engineers of national reputation, superintendent of manufacturing; for last five years works manager, construction engineer on new works and equipment and plant manager for large manufacturers of mechanical goods and plated ware, desires position where experience would be of value. Available June first.

D-70 Mechanical engineer, age 33, with broad experience in the design and construction of water tube boilers, desires position in similar capacity, or as chief engineer or sales engineer.

D-71 Member, age 38, 16 years experience in mechanical, and structural work of great variety. Expert on economical and unique arrangements for handling coal, ore, ash and other materials; experience in economical plant lay outs and mill building design, wishes position with consulting, contracting engineer or industrial plant. Will take position at reduced salary till ability is proven.

ACCESSIONS TO THE LIBRARY

WITH COMMENTS BY THE LIBRARIAN

This list includes only accessions to the library of this Society. Lists of accessions to the libraries of the A.I.E.E. and A.I.M.E. can be secured on request from Calvin W. Rice, Secretary of Am. Soc. M. E.

ABRIDGED LIST OF OFFICERS AND COMMITTEE CHAIRMEN¹

JOHN A. BRASHEAR, *President*

CALVIN W. RICE, *Secretary*

Finance Committee, R. M. DIXON

House Committee, S. D. COLLETT

Library Committee, L. WALDO

Committee on Meetings, J. H. BARR

Committee on Membership, W. H. BOEHM

Publication Committee, C. I. EARLL

Public Relations Committee, M. L. COOKE

Research Committee, R. C. CARPENTER

Committee on Constitution and By-Laws, JESSE M. SMITH

LOCAL MEETINGS

Atlanta: Earl F. Scott

Boston: H. N. Dawes

Buffalo: David Bell

Chicago: S. G. Neiler

Cincinnati: J. B. Stanwood

Los Angeles: Walter H. Adams

Milwaukee: L. E. Strohman

Minnesota: Wm. H. Kavanaugh

New Haven: H. B. Sargent

New York: Edward Van Winkle

Philadelphia: H. E. Ehlers

San Francisco: C. R. Weymouth

St. Louis: Edward Flad

¹ A complete list of the officers and committees of the Society will be found in the Year Book for 1915, and in the January and July 1915 issues of The Journal

IMPORTANT ARTICLES IN THE JOURNAL

CONTRIBUTED BY LOCAL SECTIONS, 1914-1915

ASIDE from the Spring and Annual Meetings of the Society, local meetings are now being held in 14 cities throughout the country. These local meetings bring a large amount of valuable information to the membership through the columns of *The Journal*. Among the articles which have appeared or which are to appear during the present fiscal year, are the following:

- Brake Performance on Modern Steam Railroad Passenger Trains, S. W. Dudley, November, 1914.
- Recent Developments in the Manufacture of the Diesel Engine, H. R. Setz, December, 1914.
- Panic Economies and Emergency Problems with Especial Reference to the Present Industrial Situation, F. A. Waldron, December, 1914.
- Spaulding-Drum Power Development, John A. Britton, April, 1915.
- Recent Developments in Steam-Electric Generating Stations, John Hunter, April, 1915
- Gas Producers with By-Product Recovery, Arthur H. Lynn, May, 1915
- Modern Steels and Their Heat Treatment, Robert R. Abbott, May, 1915.
- A Proposed System of Classifying and Digesting the Records of the Society, Edwin J. Prindle, May, 1915.
- Boston Symposium on Employment and Education, Walter C. Fish, William B. Hunter, Prof. Thomas N. Carver and Henry S. Dennison, May, 1915.
- Refrigeration with special reference to Ice Making as a By-Product of Central Stations, Heywood Cochrane (in preparation).
- Application of Engineering Methods to the Problems of the Executive, Director and Trustee, Dr. Hollis Godfrey (in preparation).
- Modern Electric Elevators and Elevator Problems, David Linquist (in preparation).
- A Novel Method of Handling Boilers to Prevent Corrosion and Scale, Allen H. Babcock (in preparation).
- Engine-Driven *vs.* Turbine-Driven Units in Small Capacities, A. C. Wood (in preparation).
- Diesel Engines and Their Application to Southern California, Prof. Walter H. Adams (in preparation).
- Interesting Features in Design of Connors Creek Plant of Detroit Edison Co., Prof. C. F. Hirshfeld (in preparation).
- Engineering Problems Arising in the Transportation of Natural Gas, Jas. P. Fisher (in preparation)

The variety of topics treated in these meetings is indicated in the following classification :

Power Plant	..	5	meetings	Elevators.	..	1	meeting
Industrial Management	..	3	"	Metals and Metallurgy.	..	1	"
Gas Power....	..	3	"	Refrigeration and Ice-Making	1	"	
Railroad Equipment...	..	1	"	Classifying and Indexing			
Gas Engineering.....	..	1	"	Technical Matter.	..	1	"

This emphasizes the importance of the local meetings as factors in the development of the usefulness of the Society and of *The Journal*. They are of direct benefit to members in different localities in not only extending the advantages of the technical meetings, but also by developing a large amount of original engineering data that would not otherwise be accessible. The hearty coöperation of the membership is urged in this development.

THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS
29 West Thirty-ninth Street, New York

PRICE 35 CENTS A COPY, \$3.00 A YEAR; TO MEMBERS AND AFFILIATES, 25 CENTS A COPY, \$2.00 A YEAR, POSTAGE TO CANADA, 50 CENTS ADDITIONAL; TO FOREIGN COUNTRIES, \$1.00 ADDITIONAL

C 55. The Society as a body is not responsible for the statements of facts or opinions advanced in papers or discussions.

Entered as second-class matter, January 4, 1912, at the Postoffice, New York, N. Y., under the act of March 3, 1879

COMING MEETINGS OF THE SOCIETY

May 11, New York. Subject: Metal Spray Processes in Engineering and Art, by John Calder.

May 14, Chicago, Ill. Subject: Electric Locomotives, by A. H. Armstrong, Assistant Engineer, Railway and Traction Department, General Electric Company.

May 19, St. Louis, Mo. A joint paper by several of the heads of departments at Washington University on Duration and Contents of an Engineering Course of Study.

June 9, St. Louis, Mo. Subject: Needed Improvements in Specifications, by J. B. Emerson.

Spring Meeting, Buffalo, N. Y., June 22-25. See page V.

THE JOURNAL OF THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS

Volume 37

May 1915

Number 5

THE SPRING MEETING

THE SPRING MEETING, to be held at Buffalo June 22 to 25, is the first general meeting of the Society to occur in this city, although there has been one meeting at Niagara Falls. While Buffalo is a beautiful city, always attractive to visitors and of particular interest to engineers because of its diversified manufacturing, part of one day will be spent at Niagara Falls so that all

may have an opportunity to enjoy as well the many attractions of this point of national interest. The month of June is the finest time of the year in which to visit this section of the country and the outdoor surroundings of Buffalo and the beautiful Federal Reservation at Niagara Falls will be at their best.

The arrangements for the entertainment of the Society are in the hands of a large local committee of which David Bell is Chairman, James W. Gibney, Vice-Chairman, C. A. Booth, Secretary, and C. H. Bierbaum, Treasurer. The Engineering Society of Buffalo is to join with our own members and with engineers generally in the city as hosts of the occasion.

The headquarters during the meeting will be at the Hotel Statler, where most of the sessions and entertainment features will be held. As usual, registration will begin on Tuesday (June 22) and on Tuesday evening there will be an informal reception with an address of welcome by Mayor Louis Fuhrmann of Buffalo. A welcome will also be extended on behalf of the manufacturing interests of the city. Dr. John A. Brashear, President of the Society, will respond, after which the evening will be spent informally and a buffet luncheon will be served.

On Wednesday morning, bright and early, the party is to be conducted to Niagara Falls in time to hold the opening session there, including the business meeting, for which purpose the large auditorium of the Shredded Wheat Biscuit Company has been offered.

It is customary at Spring Meetings for local engineers to provide papers for one session, and these papers for the Buffalo meeting will be read at the Wednesday morning session. During the session the ladies of the party will have an opportunity to inspect the Shredded Wheat factory and the plant of the Falls Chocolate Company, both of exceptional interest.

The afternoon will be available for the enjoyment of the beauties and grandeur of Niagara Falls or for visiting any of the industries that have grouped themselves in this city of 50,000 population. Unfortunately, a large number of these plants consider their operations in the nature of secret processes and visitors, especially technical visitors, are not granted admittance. However, some of the factories and the various power stations will be open for inspection. There will be time for those who desire to do so to take the trip of the Gorge Route.

The return to Buffalo will be in time for the lecture on Wednesday evening to be given by Dr. F. H. Newell, formerly Chief of the U. S. Reclamation Service, who has recently spoken so acceptably at several meetings of engineers in different cities and before student sections of the Society. The address will be on The Engineer as a Citizen and will be a presentation of the duties and standing of the engineer in his relation to the public. It will be illustrated by a remarkably fine collection of colored lantern slides illustrating the important work which the government has done in reclaiming the great areas of arid land in the West.

On Thursday morning there will be two simultaneous sessions for the discussion of papers, and the afternoon will be free for visiting the manufacturing plants in Buffalo. On this afternoon, special entertainment is to be provided for the ladies in the way of an automobile ride, with tea served either at the Country Club or the Automobile Club. During the ride there will be opportunity for visiting points of interest, such as the Roycroft Shops at East Aurora, where the Roycrofts engage in the arts of bookmaking, printing, the making of craftsman furniture and various ornamental products. Ladies desiring to visit the Larkin factory also may do so.

Copyright, Detroit Publishing Co.

GATES CIRCLE, BUFFALO

On Thursday evening, the usual dance and reception, which is one of the features of the Spring Meeting and always a delightful occasion, will be held at the Hotel Statler.

On Friday morning the final professional session of the meeting will be held, and the afternoon again will

be left free for inspection trips.

A list of the papers which have already been selected by the Committee on Meetings for presentation at the Spring Meeting with a summary of their contents is given elsewhere in this number. These papers are of a high order of merit and are miscellaneous in character, treating of a variety of subjects. They will be printed in pamphlet form well in advance and will be distributed at the meeting as usual. Any members who desire copies in advance may obtain them upon *application to the Secretary*.

A brief summary of the industries of Buffalo and vicinity and of features of interest both at Buffalo and Niagara Falls are given below, and members and their friends will be cordially welcomed at any of these places.

BUFFALO AND NIAGARA FALLS AND THEIR INDUSTRIES

THE ENGINEERING SOCIETY OF BUFFALO

Of first interest to visiting engineers will be the Engineering Society of Buffalo which, with local members of The American Society of Mechanical Engineers, has extended

Copyright, Detroit Photographic Co.

THE WHIRLPOOL RAPIDS, NIAGARA FALLS

MEMBERS AND GUESTS ARE INVITED TO SPEND WEDNESDAY OF THE SPRING MEETING AT NIAGARA FALLS

PLANT OF LACKAWANNA STEEL COMPANY, BUFFALO

the cordial invitation to visit Buffalo. The Buffalo Society was formed only three years ago but already has 320 members, of which 50 are members of the Am. Soc. M. E. While an independent body, it feels that it owes a large measure of loyalty to the national Society and does all in its power to encourage the local members to join. It is broadly representative of all engineering activities, including in its membership civil, electrical, and mining engineers, chemists and architects. Meetings are held every two weeks.

BUFFALO FOUNDRY AND MACHINE COMPANY

This plant has a capacity in its cupolas for melting 55 tons per hour and many castings up to and over 100 tons weight are made, and besides there is ample equipment for machining large pieces. One of the specialties is the production of vacuum apparatus for all purposes, including small laboratory experimental devices and machines with a volumetric capacity as great as 5 ft. in diameter by 12 ft. long. Over 60 years ago David Bell, Sr., evolved his first designs of steam hammers which have since been another specialty of this company and are built in sizes up to 200 tons in weight.

THE LACKAWANNA STEEL COMPANY

This is generally considered to be the largest independent steel producing plant in the world. It covers approximately 1500 acres along the shore of Lake Erie, near Buffalo, and gives employment to about 12,000 men. The annual payroll expenditure is over \$10,500,000 and the gross production about 1,250,000 tons.

Of interest to the members of the Society will be the Lackawanna descaling process for rails which formed the subject of a paper at the last annual meeting by Robert W. Hunt of Chicago, Ill. Visitors should also see the new W-9 Merchant Mill which is the latest word in planning and construction. This design has been the result of extensive study of other mills at home

and abroad. One interesting feature that always strikes the visitor is the "Safety Arch." It will be noticed in the photograph on page IX that there are tags extending on each side of the frame. These bear the names of the different departments and when all is well, a small metal American flag flies alongside each, but if an accident has happened during the preceding 24 hours, the flag is covered with a black sleeve. Great interest is taken by the men in keeping their flags flying and this arch has been of decided value in reducing the number of accidents.

LARKIN COMPANY

In 1878, the Larkin Company conceived the idea of selling directly from factory to ultimate consumer. The idea prospered and from a small beginning in a factory having an area of 3000 sq. ft. their business has grown until today it is housed in a plant containing some 40 acres of floor space. This immense factory is devoted to the production

Copyright, Detroit Publishing Co.

SHILTON SQUARE, BUFFALO

of soaps, perfumes, kitchen necessities and the staple groceries such as tea, coffee, sugar and spices.

The office building where the large and extremely complicated affairs of the Company are conducted typifies the last word in office system. Particular attention has been paid to lighting by direct daylight during the day and by indirect illumination during the evening. Phonograph dictation is used. Desks and chairs are all designed so that they take up the least possible floor space and allow for maximum cleanliness. Chairs swing under the desks when not in use, thus leaving the aisles practically clear. Much of the furniture is of pressed steel in a special design.

This careful attention to detail is followed throughout the factory. One of the most interesting things to visitors is the system whereby Larkin products are distributed to all parts of the country. The shop floors are divided into sections, each named for a State in the Union. Box cars are taken on large elevators and lifted up to the floor which is named for the State that is their ultimate destination. Here the car is completely loaded, thus avoiding excessive handling and damage by trans-shipment.

THE WICKWIRE STEEL COMPANY

The Wickwire Steel Company operates a small but very high quality blast furnace plant within a very short distance of Buffalo. Their plant is very modern, having been erected in 1910. The output is in the neighborhood of 350,000 tons of iron a year. The company owns its ore properties, and also a fleet of large lake carriers for transporting the ore to the plant. They make a special point of producing special analyses of iron, and their methods of handling raw material to insure that the analysis shall be as specified will prove of much interest to visitors.

PRATT AND LAMBERT COMPANY

The Pratt and Lambert Company is one of the world's largest varnish manufacturers, and their plant in Buffalo offers much that is of interest. Their "Vitrinite" white enamel, which can be brushed within a short time after its application, is of particular interest to engineers, and the company extends a cordial welcome to visitors. This company is one of the largest national advertisers, and maintains a complete printing equipment capable of handling not only the ordinary run of work but elaborate color printing as well.

SNOW STEAM PUMP WORKS

This is one of the plants of the International Steam Pump Company, and was originally established in 1889. Since then it has enlarged to many times its original capacity. The Indianapolis pumping station built in 1895 was equipped with what was, at that time, the largest pumping engine in the world, built by this company. In 1900 this concern took up the manufacture of gas engines, concentrating attention on the largest sizes only. The total horsepower of the gas engines built by them up to 1914 was 211,000.

Prior to the expiration of the Diesel patents, this company had been investigating oil engines and in 1912 they began to produce two- and four-cycle Diesel oil engines, both of the horizontal and vertical type. These are also made chiefly in the largest sizes and their design represents the latest developments of this work in the United States.

A visit to the Snow Steam Pump Works should certainly

be taken by those interested and a cordial invitation is extended.

PIERCE-ARROW MOTOR CAR COMPANY

The Society is invited to make the works of this company one of the points of interest to be visited. This is considered to be one of the most up-to-date factories of the type in the country and its product is confined strictly to high grade automobiles and motor trucks. It has an area over 1,000,000 sq. ft. The ideals of the company are high and engineers will be impressed with the methods used to insure that the materials employed are up to specifications. Forgings and castings, although coming in in large quantities, are all carefully inspected and tested with the scleroscope or Brownell machine to ascertain that the heat treatments have been properly carried out. In addition, a laboratory and metallurgical department are maintained for research into the latest developments and uses of materials. The company does not do its own forging or foundry work, but has large machine shops, firing rooms and assembling departments.

The product consists of pleasure cars in three models, 38, 48 and 66 h.p. and also two capacities of motor trucks, 2-ton and 5-ton, equipped with special devices for handling all kinds of loads. These trucks will be of especial interest to engineering contractors, by whom they are largely used.

The Pierce-Arrow Company is also noted for its welfare work, and those interested in this line of endeavor should not miss the opportunity of seeing their large kitchen and dining hall and other conveniences that have been provided for the use of the employees. Altogether some 4000 men are employed.

SOME BUFFALO FOUNDRIES

To those interested in foundry work, the plant of the Pratt and Letchworth Company will well repay a visit. This is an exceedingly large foundry, specializing in freight car and locomotive castings in malleable iron and steel. The plant, although an old one, is constantly being brought up to date.

Other foundries are the Bingham and Taylor Company, also a large company, which is just now developing a process for making small steel castings.

The Aluminum Castings Company has a large plant devoted to the production of very large but thin aluminum castings.

The D. W. Sowers Manufacturing Company specialize in the casting of small, high grade cylinders for gas and oil engines. Their product is being used by the Curtis Aeroplane Company.

THE BUFFALO FORGE COMPANY

This is one of Buffalo's largest industries. The company specializes in the manufacture of ventilating and drying apparatus under the Carrier patents. Mr. W. H. Carrier, member Am. Soc. M. E., has installed his humidifiers in many varied industries and it is stated that his system has greatly facilitated the manufacture of cotton and woolen goods in this country.

THE SIMONDS MANUFACTURING COMPANY

Lockport is a small city some 25 miles from Buffalo and

is easily reached by trolley car. The Simonds Manufacturing Company located there, manufactures saws, files and steels and have a large plant which is well worth a visit.

connection with this, such as the use of fluid compression in the manufacture of high grade armor plate in conjunction, of course, with the Simonds Company's well known

MEMBERS ARE CORDIALLY INVITED TO VISIT THE INDUSTRIAL PLANTS OF BUFFALO

The location is near enough to the Falls to make electric power easily available, and this company is now installing a large electric furnace for the production of a very high grade of tool steel. There are many special features in

quality of tools, and a visit to the plant will be of interest.

While in Lockport the visitor should not miss the opportunity of inspecting the immense locks on the barge canal which connects Lake Erie with the Hudson River.

THE ROYEROFT SHOPS

Another place in the vicinity of interest especially to the visiting ladies, is East Aurora, a beautiful country town only 18 miles from Buffalo, the home of Elbert Hubbard and the Roycroft Shops. The Roycrofters form a community operating their own hotel, or rather inn, and their own farm. Mr. Hubbard has advanced ideas on the responsibility of the employer towards his work and workmen which he attempts to carry out in all sincerity. This institution is unique in the United States and never fails to interest visitors and to provide them with considerable food for thought.

IN GENERAL

There are so many varied industries in Buffalo that it is impossible to mention all of them, but visitors have only to make known the factories they wish to visit and the committee of the Buffalo Engineering Society, which is looking after this matter, will do their best to enable them to visit the plants in which they are specially interested.

NIAGARA FALLS

Of first interest from an engineering standpoint at Niagara Falls are the power plants and here are located also the many electro-chemical industries, which, however, in general, are not open to the public. One-half million electric horse power are being generated and supplied at low cost to districts as far as 250 miles distant. This is the home of the Shredded Wheat Biscuit Company, famous throughout the country because of its model factory, a favorite place for visitors and a meeting place for societies holding conventions at Niagara Falls. The plant of the Falls Chocolate Company is also of interest.

At this time of the year the natural attractions of Niagara Falls, the Park and Goat Island constituting the Government Reservation, the beautiful foliage, the wooded slopes extending down to the rapidly rushing waters in the Gorge will be at their best. The Gorge trip, extending on both sides of the Gorge and on the American side, practically at the water's edge, is always an attraction of interest.

ABSTRACTS OF PAPERS TO BE PRESENTED AT THE SPRING MEETING

LAPS AND LAPPING

By W. A. KNIGHT AND A. A. CASE

This paper gives details of tests of abrasives when used for lapping operations with the object of determining the effect on the rate of cutting with different combinations of abrasive, lubricant, and lap material. The tests were made with hardened steel specimens, on a machine built especially for the purpose.

Comparative results were obtained with emery, alundum, and carborundum used in connection with lard oil, machine oil, gasoline, kerosene, turpentine, alcohol, and soda water. The lap materials were cast iron, soft steel, and copper.

The investigation shows that in general there is a lubricant that will give best results with a given combination of abrasive and lap. Thus, emery on the cast lap gives best results with gasoline and kerosene, while lard oil and machine oil are distinctly inferior. On the other hand, with carborundum on the steel and copper laps, lard oil and machine oil do the best work of any of the lubricants tested, while gasoline and kerosene do the least efficient work with these combinations. Lard oil invariably gives a higher rate of cutting than machine oil.

Carborundum usually gives a higher rate of cutting than the other abrasives, but it also wears the lap faster. The tests show that carborundum wears the lap surface about twice as fast in proportion to the amount ground from the steel specimen as does emery, and the wear with alundum is one and one-fourth times that with emery. Also, the wear of the copper lap is about three times, and the steel one and one-fourth times, that of the cast iron. This wear is shown to be inversely proportional to the hardness of the lapping plates, as shown by the Brinell test.

Comparisons were made, too, between the "wet" and the "dry" methods of lapping. In dry lapping much depends on the manner of charging the lap. Results show that with the wet method the rate of cutting is two to six times as fast as with the dry, depending on how the lap was charged.

MODEL EXPERIMENTS AND THE FORMS OF EMPIRICAL EQUATIONS

By E. BUCKINGHAM

The object of this paper is to illustrate the use of the dimensional method of reasoning in devising empirical equations and in planning and interpreting experiments,—particularly experiments on models.

After stating the principle of the method in the form of a convenient theorem application is made to the familiar problem of flow through smooth pipes so as to illustrate the working of theorem in a well known case. The next application is to the resistance of totally immersed bodies such as submarines; it leads to the notion of dynamical similarity and the interpretation of experiments on models. Application to the air resistance of projectiles shows how compressibility of the resisting medium is to be allowed for when the speed is high. Application to the screw propeller illustrates the treatment of a slightly less elementary problem, involving more variables, and shows how approximations, which are often unavoidable, may be introduced. The last problem treated is introduced for the sake of showing that the dimensional method is not restricted to the field of mechanics. It deals with an elementary case at heat transmission, and in the course of it some new points are brought out with regard to the practical working of the details of the dimensional method.

These illustrations—which might be multiplied almost indefinitely—have been selected with a view to elucidating some of the various devices which are of use in the practical application of new problems.

The method of reasoning is purely algebraic and therefore, in itself, rigorous. But while it cannot supply any new facts, because it is only mathematical and not physical, it often illuminates facts already known in a quite surprising manner, and sometimes permits our analysing and coördinating experimental data which without this guide seem hopelessly confused or contradictory.

RATIONAL DESIGN AND ANALYSIS OF HEAT
TRANSFER APPARATUS

BY E. E. WILSON

The results of tests of heat transfer apparatus have been so inconsistent that the formulation of rational bases for design is precluded. This lack of agreement leads to the conclusion that some variable has been neglected, and a study of the results of tests on feed-water heaters and condensers leads to the belief that this variable is the viscosity of the circulating water. Since the accepted law for heat transfer is of the same general form as that for the resistance to flow in pipes, it seems likely that there is some close relation. It also seems probable that the effect of viscosity is of the same general character in each case, and on this assumption the published results for heat transfer are corrected in the same manner as are the results of Osborne Reynold's work on the resistance in pipes to flow of water through them. With this correction the results are reconciled, not only in an individual case, but for different experimenters as well.

If now these results as corrected, are put in the form of resistances to heat transfer, a linear relation is found to exist between the resistance and the reciprocal of the water velocity. The correction for viscosity may be put in this same form as a function of temperature. The resistance may then be evaluated in terms of its component parts and reduced to the form of an equivalent film of water of known thickness. These linear expressions may now be incorporated in a form giving the area of the heating surface required to transmit a given quantity of heat under the given flow conditions, in a condenser or feed-water heater. This expression seems rational in form and applicable throughout the range of practice, and in addition it seems possible through the use of the relations established to determine by experiment a similar expression for the resistance to heat transfer in other types of apparatus.

INFLUENCE OF DISK FRICTION ON TURBINE
PUMP DESIGN

BY F. ZUR NEDDEN

The mathematical survey of the problem leads to these conditions for a minimum loss through disk friction:

- a Smoothness (polish) of both disk and casing. Roughness of either is equally detrimental.
- b Smallest possible surface of both. Excessive extension of surface is equally detrimental whether it is the surface of the disk or of the casing.

c Outward indication of attainment of minimum is the fact that waste-water rotates half as fast as impeller.

A gyrostatic pressure is generated by the rotation of the waste-water and added to static pressure prevailing at periphery of impeller.

From the influence of the width of the impeller it follows that it is important to keep the thickness of metal at the periphery as small as possible. Protruding rims are objectionable.

The influence of the ordinary roughness of non-machined castings has no perceptible effect on the efficiency except with high lift pumps. Painting or japanning the surfaces generally seems less desirable than machining them with a medium heavy cut. High polish seems wasted. The experiments verify conclusion of mathematical survey.

The influence of viscosity is proportional to its fifth root; yet, it is responsible for an improvement in the efficiency of hot-water turbine pumps. The effect of pumping heavy oil and tarry liquid is estimated. The influence of fluid density is almost exactly proportional to the specific gravity.

The loss through disk friction constitutes a constant percentage of the useful power at all speeds in one and the same pump. Generally its percentic value grows with the value of

Head per stage at constant speed, and diminishes with increasing speed and constant ratio.

Capacity Head per stage. High Capacity

heads are more economically produced by high speeds or a greater number of stages than by increasing the diameter of the impellers, but the number of stages should be left to the discretion of the makers, not fixed by specifications. A steep angle between impeller blades and the tangent at the periphery serves very considerably to improve the efficiency owing to indirect reduction in disk friction losses, especially in high lift pumps.

The disk friction reaches a minimum for a certain width of the waste water chamber which is about $\frac{5}{8}$ in. for disks of 12 in. diameter. The increase with increasing width is due:

- a To the increase in retarding surface
- b To the induction of secondary or induced hydraulic currents.

Concentric ribs are advantageous, radial ribs are detrimental.

In single-stage pumps the rotation of the waste water reduces the tendency for leakage by about 20 to 35 per cent. In multistage pumps the same influence may even increase the leakage.

Inequality in shape or roughness of the waste-water chambers on both sides of the impellers produce a gyrostatic axial thrust due to disk friction which can assume very considerable values. The direction of this thrust is indicated by the rule. The impeller is drawn to the side where the waste-water rotates farthest.

A STUDY OF AN AXLE SHAFT FOR A MOTOR TRUCK

By JOHN YOUNGER

The shaft in question is the driving shaft on a large motor truck which transmitted 16½ h.p. at 27 rev. per min., and gave trouble by breaking after some service. The conditions of the shaft were investigated very closely and the methods by which, first of all the design was improved, are given in detail. It was found, however, that this was not sufficient and the only problem left was as to whether the material could not be improved. It was impossible to increase the size of shaft without running into various difficulties and experiments were made to improve the strength of material. It was finally found that by suitable heat treatment the elastic limit of the shaft could be raised to 175,000 lb. per sq. in. Experience with these heat-treated shafts has now extended over a period of two years, during which the results have been perfectly satisfactory.

CORRUGATED FURNACES FOR VERTICAL FIRE TUBE BOILERS

By F. W. DEAN

This paper discusses the advantages of using corrugated furnaces for vertical boilers, and gives as advantages the absence of staybolts and a slight amount of elasticity. It also speaks of the different sizes that can be obtained and the horse power of boilers that can be realized from furnaces of the largest size now made, and states some points to be borne in mind when making a design of such furnaces. It also speaks of their behavior under hydrostatic test, and of the proper method of flanging the fire door opening. The paper gives illustrations of two boilers with such furnaces that are now in use.

THE EFFECT OF RELATIVE HUMIDITY ON AN OAK TANNED LEATHER BELT

By WILLIAM W. BIRD AND FRANCIS W. ROES

A careful study of the effect of changes in the relative humidity on a 4-in. single oak tanned leather belt was made and the results analyzed.

The effect most closely connected with the use of leather belting for power transmission was found to be in the lengthening of the belt with an increase in the relative humidity. This change in the length of the belt reduces the belt tension provided the distance between the pulley centers remains constant. This effect varies with the relative humidity, but is greater at high temperatures and less at low temperatures, but not in direct proportion to the absolute humidity.

The conclusions are that the relative humidity should be considered when a belt is tightened, the initial tension being made less for high relative humidities and greater for low; that a spring or gravity tightener should be used if it is desired to eliminate the effect of changes in humidity.

Leather is more or less of an uncertain material, the treatment and quality varies and hence these conclusions should be considered only in a general way.

THE RELATION BETWEEN PRODUCTION AND COSTS

By H. L. GANTT

In the past it has been pretty common practice to make the product of a factory at a portion of its capacity bear the whole expense of the factory. This has been long recognized by many to be illogical, but so far there has not been presented a rational theory as to what proportion of the expense such a product should bear.

Mr. Gantt offers the theory that the amount of expense to be borne by the product, should bear the same ratio to the total normal operating expense, as the product in question bears to the normal product, and that the expense of maintaining the idle portion of the plant ready to run is a business expense not chargeable to the product made.

This latter expense is really a deduction from profits, and shows that we may have a serious loss on account of having too much plant, as well as on account of not operating our plant economically.

DESIGN OF RECTANGULAR CONCRETE BEAMS

By HOWARD HARDING

The resisting moment of a reinforced concrete beam may be represented by the formula $M = Rbd^2$ where b is the breadth, d is the depth and R is a numerical co-efficient depending upon $E_c \div E_s$, f_c , f_s , and the percentage of steel reinforcement.

The paper outlines the development of two graphical diagrams, for the direct solution of the above equation. By their use the usual "cut and try" operations are eliminated. The diagrams are of the logarithmic form and since all the lines are straight and either horizontal, vertical, or at about forty-five degrees, the mechanical work of determining intersections is greatly facilitated.

By use of the first diagram the dimensions of beams just strong enough to withstand safely any desired bending moment are determined.

The second diagram gives factors by which the dimensions obtained from the first diagram are multiplied in order to correct for the bending moment due to the dead weight of the beam itself.

The beam should be checked for shearing stresses, and shear reinforcement added where necessary.

At the end of the paper a typical example is worked out in detail and a suggested form of computation is given.

SOME MECHANICAL FEATURES OF THE HYDRATION OF PORTLAND CEMENT AND THE MAKING OF CONCRETE AS REVEALED BY MICROSCOPIC STUDY

By NATHAN C. JOHNSON

Little has been actually known of the basic relations between the various materials entering into the composition of concretes. With a view to determining these, methods similar to those employed in the microscopic study of the structure of steels have been applied to a study of concretes.

As a result, new knowledge has been obtained with re-

gard to the functions of the various dissimilar ingredients of the concrete and as to the detrimental effects of foreign impurities, such as entrained air; and explanation is offered as to why, even with the best of materials, only low-strength structural material is obtained.

The production of binding substance, through the hydration of cement is also investigated by the microscope and a surprisingly low efficiency of use is found to obtain in all concretes. This relates further to the permanency of under-water concretes and reasons for failures are demonstrated and explained.

SURFACE CONDENSERS

BY CARL F. BRAUN

This paper presents the matter of the surface condensation of steam in connection with the most recent developments in condenser design and construction. The application of the logarithmic mean temperature difference between the steam and cooling water is taken up with reference to the counter current and parallel current system of circulation and a number of curves developed for the determination of the mean temperature difference.

The conditions affecting the variation of heat transfer through condenser tubes are carefully analyzed and presented in an original manner.

The main feature of the paper is its presentation of the principles of condenser design which are held to be correct theoretically and mechanically and the application of the principles involved to recent developments in the construction of condensers. The matter of steam circulation throughout the condenser is thoroughly discussed and the great importance of this point dwelt upon. The paper in the whole though presenting nothing startlingly new, discusses an old subject in a new and original way and points out the laws along which the modern surface condenser is developed.

COUNCIL NOTES

At the meeting of the Council on April 9, 1915, the President announced the following appointments: Tellers of Election, H. A. Hey, Chairman, H. P. Hayes and R. H. Kirk; Committee on Classification of Engineering Literature, F. R. Low, Chairman, L. P. Breckenridge, W. W. Bird, A. E. Forstall and E. J. Prindle; this committee to coöperate with the Committee of the American Gas Institute, and also to report on a similar matter from a recent meeting of members in New York and referred by the Council to this committee.

Coöperation has been requested by this Society in the movement to form a reserve corps of civilian engineers representing all branches of the engineering profession. The Council recorded its sympathy with the proposed movement and voted that the President appoint a committee of five to coöperate with the War Department and committees of the other societies, who have taken similar action.

The Committee on Public Relations, and the Society's representatives on the Conference Committee of the National Engineering Societies, are authorized to be present at the State Constitutional Convention, and

to coöperate with the other engineering societies at conferences.

A communication was received from the American Association for the Advancement of Science asking that this Society assist in formulating plans to improve the present method of securing expert testimony.

VOTED: That the Society coöperate with other technical societies in any movement having for its object better practice in the use of the expert testimony of engineers in court proceedings, and that a special committee of five be appointed by the Chair, to carry on such coöperative work, such a committee to include in its membership one member experienced in the use of expert testimony in patent causes, one in the use of expert testimony of engineers in accident cases, and one in the use of experts in valuation cases.

The names of A. R. Baylis, A. M. Houser, Julian Kennedy and W. M. White were announced as the additional members of the Committee on Hydraulic Flanges of which the Council had named H. G. Stott as Chairman.

VOTED: To approve and appoint as a local committee on meetings of the Society in Worcester, Mass., the following, duly nominated at a regularly called meeting of members in Worcester and vicinity: P. B. Morgan, Chairman; E. H. Reed, Secretary; C. F. Dietz, F. W. Parks and H. P. Fairfield.

Prof. Frederick R. Hutton reported that the Committee on the Sir William H. White Memorial had forwarded a draft for 60 pounds, to the Committee in England in charge of this memorial.

VOTED: That a committee of five be appointed by the Chair to formulate general principles for the guidance of those who may serve the Society in a representative capacity and particularly when dealing with public questions.

APPLICATIONS FOR MEMBERSHIP

Members are requested to scrutinize with the utmost care the following list of candidates who have filed applications for membership in the Society. These are sub-divided according to the grades for which their age would qualify them and not with regard to professional qualifications, i.e., the age of those under the first heading would place them under either Member, Associate or Associate-Member, those in the next class under Associate-Member or Junior, while those in the third class are qualified for Junior grade only. The Membership Committee, and in turn the Council, urge the members to assume their share of the responsibility of receiving these candidates into the Membership by advising the Secretary promptly of any one whose eligibility for membership is in any way questioned. All correspondence in regard to such matters is strictly confidential and is solely for the good of the Society, which it is the duty of every member to promote.

These candidates will be balloted upon by the Council unless objection is received before June 10, 1915.

Promotion from Junior	1

GAS PRODUCERS WITH BY-PRODUCT RECOVERY

BY ARTHUR H. LYMN,¹ LONDON, ENGLAND

Non-Member

THE art of generating producer gas from coal is a very old one, but the development of the simultaneous recovery of the valuable by-products is comparatively recent, having been confined to the last twenty-five years or so. The object of this paper is to present a historical resumé of this development in Europe, and also to outline some of the latest features of the Lymn system of by-product recovery for which the author has been responsible.

The early attempts in Europe to recover the by-products of the producer gas process are generally recognized to have been made in Great Britain. In that country the knowledge that the treatment of fuel by a mixture of steam and air (the former in excess) would convert a large percentage of the nitrogen contained in the coal into ammonia was first applied in practice on a large scale. The details of a plant to operate on this principle had always been worked out by Messrs. Young and Beilby in England and Grouven in Germany among other investigators.

The gas producer designed by Young and Beilby differed in operation from the ordinary by-product gas producer in that it was heated from the outside. The coal was distilled in the upper part of the producer or retort and the tar

Carbonic acid.....	16.6 per cent
Carbonic oxide.....	8.1 per cent
Methane	2.3 per cent
Hydrogen	28.6 per cent
Nitrogen	44.4 per cent

Although their retort was heated from the outside instead of the air and steam blast being superheated, it will be seen that the results claimed by them as to ammonia were not far short of what we realize to-day. The gas composition,

FIG. 1. YOUNG AND BEILBY'S BY-PRODUCT GAS PRODUCER

vapors passed down through red hot coke and were (it was claimed) decomposed into permanent gas and ammonia. The coke in the lower half of the producer was burned in a mixture of steam and air and the resulting gases, together with the gaseous products of the coal distillation, passed out of the producer by way of exits at the middle. The arrangement is shown in Fig. 1.

It is particularly interesting to note that, as far back as 1883, Young and Beilby claimed to recover in the form of ammonia from 60 to 70 per cent of the total nitrogen in the fuel and that the percentage composition of their gas was:

too, was practically the same as that of the gas which has since become so widely known as Mond gas and which has the following percentage composition:

Carbonic acid.....	14 to 16 per cent
Carbonic oxide.....	10 to 12 per cent
Methane	2 to 3 per cent
Hydrogen	25 to 29 per cent
Nitrogen	Difference

The above makes it obvious that Dr. Mond was not the first investigator to produce gas of this composition.

It is now rather more than twenty-five years since the late Dr. Ludwig Mond first put into commercial practice the process described in his British Patents No. 3821 of 1883 and 8973 of 1885, of gasifying fuel by means of steam and air and simultaneously recovering the ammonia. His first plant was installed at the works of Brunner, Mond and

¹ Sanctuary House, Tothill Street, Westminster, S. W., London, England.

FIG. 2. MOND SYSTEM PRODUCER GAS AMMONIA RECOVERY PLANT

Co., Northwich, England, and its capacity was developed to some 200 tons a day. Unfortunately this plant was not in a good position to be photographed, but a diagram of it is given in Fig. 2.

The Mond producer was rectangular in section and was formed with a kind of double chamber. Its operation was similar to that of Young and Beilby, in that the coal was distilled in a downward direction in the upper part and the coke residue was gasified in the lower part, all the gases mixing and leaving the producer together. The gas was passed into a long horizontal rectangular washer and a fine spray of water was thrown into it by a series of revolving dashers. By this means a large proportion of the dust was removed, which was afterwards taken out of the water lute manually with long scoops, an irksome operation. From the washer, the gas was conducted into a high lead-lined acid tower (filled with earthenware ring tiles) where in passing upwards it came into contact with sulphate of ammonia solution trickling down. This solution contained a slight excess of sulphuric acid and deprived the gas, by absorption, of nearly all the ammonia contained in it. From this tower, the gas was passed into a similar tower, called the scrubber, where it was brought into contact with cool water for scrubbing and cooling it and it was then delivered for use.

The water, having taken up the heat of the gas, was collected in tanks from which it was introduced into the heater,

FIG. 3. MOND PRODUCER WITH SUPERHEATER

also of tower construction. It was here brought into contact with the cold air to be used in the producers, saturating this air with water vapor at from 70 to 80 deg. cent. and becoming again cooled. Then it was returned to the scrubber,

where it again took up the heat of the gas, and so on in a continuous cycle.

After this plant had been in operation for some time, it was found that, owing to the large proportion of steam

FIG. 4 MOND GAS CENTRAL STATION AT DUDLEY PORT, ENGLAND

FIG. 5 DUFF PRODUCER WITH SUPERHEATER

in the air blast, the heat value of the gas was below the desired standard and also the yield of ammonia was less than that which Dr. Mond had set out to obtain. It was therefore decided to change the design of the gas generating part of the plant so that the air and steam blast would enter the producer with a considerable degree of superheat, thus enabling a still greater excess of steam to be used. This modified design was disclosed in Mond's British Patent No. 12,440 of 1893 and is shown in Fig. 3. The producer was made circular in section instead of rectangular and its whole shell was surrounded by a jacket through which the air was passed on its way to the grate, reducing the losses from radiation and at the same time further superheating the steam and air blast. Directly contiguous to the producer was arranged a superheater, consisting of a series of parallel tubes with alternate ends connected, surrounded by a series of larger tubes forming an annular space. The gas from the producer passed through the inner tubes and superheated the steam and air blast which was passed through the annular space in a counter-current direction on its way to the producer. With this provision, the gas was found to possess a much higher heat value and a considerably increased yield of ammonia was obtained without extra fuel.

It is interesting to note that Dr. Mond, with that great courage in engineering undertakings for which he was famed in

FIG. 6 DUFF PLANT AT FLEETWOOD, ENGLAND

the days of his greatest activities, built a very large unit plant at the outset, and smaller plants in later years. This was contrary to the usual order of things, and discloses the reason for the widespread idea that by-product producer plants were only profitable when built in very large and costly units.

Among the plants built by Dr. Mond or his successors in England—The Power-Gas Corporation—the central station at Dudley Port, Staffordshire, for the distribution of Mond gas over an area of about 120 square miles, through about 30 to 40 miles of pipes, is of particular in-

terest. The author had charge of this plant for some time. The gas from this station is supplied to iron and steel works, machine shops, foundries, galvanizing works, pumping stations, enameling works and municipal electric stations. The installation had originally a capacity of 16,000 h.p., which has just recently been largely increased. A general view of this plant which is familiar to many engineers in this country is shown in Fig. 4.

The Dudley Port plant is quite unique in that it is the only central station in the world designed and built for the distribution of producer gas. The gas is sold to consumers in competition with coal, ordinary lighting gas and electricity. The advantages to be derived from taking supplies of the gas were not apparent to the public for several years, but once they had been fully demonstrated the number of consumers rapidly increased.

Up to about the year 1897, Dr. Mond was constantly endeavoring to improve his process, but after that time he appeared to be satisfied with his design and in fact in advancing years he became adverse to any material modifications. The result was that the design of the Mond plants did not advance with the times and the writer is of the opinion that in those cases in America in which Mond system plants have not been so successful as was expected, it has been chiefly attributable to this factor and to the failure to realize that a certain state of reliability and efficiency in other countries, with quite different fuels and under totally unlike conditions, is not necessarily a criterion for exactly the same results in this country.

After Dr. Mond had demonstrated the success of his process, it was not long before another worker, E. J. Duff, claimed attention. As a whole Duff's plant embodied very little to distinguish it from the Mond plant, the same process being of course carried out in the two plants. Duff's producer was of rectangular section inside, with rounded corners, and his superheater, as shown in Fig. 5, consisted of a series of parallel gas tubes with alternate ends connected, surrounded by one chamber. Baffles plates in this chamber compelled the steam and air blast to take a zig-zag path on its way to the producer. Except for this slight difference in the construction of the superheater, which, however, occasioned no difference in the action of the producer, there was practically nothing to distinguish the Duff plant from the Mond plant.

Several large plants were constructed according to Mr. Duff's designs. One of these is shown in Fig. 6. This was erected at Fleetwood, England. The photograph does not show the producers very well but conveys a good idea of the great height and size of the towers for ammonia absorption, gas cooling and air saturation. These large towers are characteristic of the plants of this construction. It is well known in Great Britain that Mond and Duff were

FIG. 7 CROSSLEY AND RIGBY PATENT AMMONIA RECOVERY PLANT

at one time in conflict in the matter of their patents, but that their interests were afterwards amalgamated into one company, The Power-Gas Corporation, formed in 1901. The patents in question have since expired in England, but it may be that some of Duff's American patents are still in force.

Messrs. Crossley Bros., of Manchester, were the next to claim material improvements, which, however, do not appear to have been realized in practice. In fact, it is the author's belief that some time ago this firm ceased altogether to build plants for the gasification of coal and the simultaneous recovery of the by-products. It is perhaps nevertheless of interest to include here a diagram of the first form of plant Messrs. Crossley Bros. adopted (Fig. 7).

Briefly the claims made for this plant were that the washing and cooling of the gases, as well as the condensing of the water vapor and the absorption of the ammonia, took place in one and the same apparatus, the ammonium sulphate liquor being utilized for the purpose of saturating the air with water vapor and the liquid being thereby cooled at the same time. As a matter of fact, in the first series of operations a washer made up of two compartments was used, and the gas would leave this apparatus in a more or less uncooled state and also practically saturated with water vapor at a comparatively high temperature. Fig. 7 does not therefore show all the necessary apparatus.

The second claim made, that is, that the air was saturated by means of the sulphate liquor, represented a very dangerous practice. A fine sulphate of ammonia liquor spray, with its excess of highly-corrosive acid, would naturally be carried forward to the superheaters, etc., and with very obvious results. Messrs. Crossley Bros., as a matter of fact, took out later a patent for the utilization of the above system in combination with a somewhat costly bed of lime, which the saturated air had to pass through, clearly to absorb its contained acid spray.

The next step in the development of this process the author feels justified in claiming to have taken himself

FIG. 9 MOORE'S THREE-PART PRODUCER

on the basis of his British Patent No. 8014 of 1908. This was an attempt to entirely dispense with the costly and irksome towers of the Mond and other plants, which became blocked up from time to time causing serious trouble and delay. The attempt was made by replacing the mechanical

FIG. 8 MOND TYPE AMMONIA RECOVERY PLANT WITH DOUBLE CHAMBER WASHERS

washer and towers by washers of special construction, which obviously could not become blocked up. Four double washers were proposed, one for washing the gas, the second for absorbing the ammonia, the third for cooling the gas and the fourth for saturating the air. This design was later modified in favor of a double-luted washer and was changed a third time by The Power-Gas Corporation for a combination of double and single chamber washers upon the same principle. An idea of the general appearance of a plant with these washers may be obtained from Fig. 8.

FIG. 10 MOORE'S PATENT SYSTEM BY-PRODUCT RECOVERY PLANT

Various modifications of ammonia recovery plants are also disclosed in patents taken out by A. B. Duff, of Pittsburgh. Notable among these is a producer with a circular grate and also a circular section superheater with four enclosed gas tubes. The former is illustrated in British Patent No. 16,164 of 1903 and the latter in British Patent No. 16,243 of 1903. These modifications have been adopted in Great Britain in two or three plants and are, I believe, working successfully with Scotch and other more or less non-caking coals.

In another design (British Patent No. 4372 of 1910) A. B. Duff claims that by passing the gas around the evaporator before entering the washers, its heat can be utilized for evaporating the sulphate of ammonia liquor. On first sight, this idea appears to be a good one, but it seems to the writer that great difficulty may be experienced in carrying it out in practice on account of the dust and tar present in the gas at this stage of the operations. Moreover, it must be borne in mind that in this design the gas is washed before it is allowed to enter the ammonia absorption tower, and that the washing water is used for saturating the air going into the producers. It therefore appears that the air will carry to the producers a not inconsiderable proportion of the ammonia which will thus be lost. The author is not aware of a plant on these lines having been built and put into operation, and is but meagrely informed concerning the earlier Duff plants built in the United States.

It may be taken that all the designs above referred to were, broadly considered, based upon what is generally

known throughout the world as the Mond process. Two different propositions for the gasification of coal and the simultaneous recovery of the by-products will now be referred to.

The first of these is that by F. J. Rowan, of Glasgow, who proposed to combine the gas producer process with the usual process utilized in lighting gas works, viz., to replace the absorption of the ammonia by acid (as is done in the Mond process) by a condensing plant. He did not propose to actually produce the ammonia in any different way, and it is obvious that since, for every ton of coal gasified, approximately 150,000 cu. ft. of gas at normal temperature and pressure, together with about 1.5 tons of excess water vapor, are produced, an apparatus for condensing the ammonia cannot be other than very excessive in size. Moreover, the gases enter the condensing plant at a temperature of 400 deg. cent. or more, at which tem-

FIG. 11 LYMN TYPE WASHER

perature their volume is multiplied several times. The condensed ammonia liquor is extremely dilute and must be distilled with lime in the usual manner adopted in lighting gas works, a not very pleasant operation. These facts make the difficulty of carrying out this proposition obvious, and the writer is not aware that any plant was built on these lines. The author himself has tried surface cooling for by-product producer gas but has found firstly, that meteorological conditions have too much influence on the result and secondly, that the apparatus required would be much more expensive owing to the large volume of gas to be dealt with and the lower rate of heat transference possible.

The second proposition is that by Quintin Moore who designed a producer divided into three parts, a lower brick-

lined part, a middle water-jacketed part and an upper air-cooled part. The arrangement is shown in Fig. 9.

By this cooling of the upper part of the producer, Moore claimed to obtain a good yield of ammonia with about half the amount of steam in the air blast. It does not seem likely, however, that such cooling can penetrate far into the fuel bed, and it should not be overlooked that other workers, in particular the late Dr. Mond, previously considered the possibility of recovering ammonia by means of merely cooling the producer, but came to the conclusion (based on sound scientific knowledge) that cooling was not the only desideratum in ammonia recovery.

FIG. 12 LYMN TYPE PRODUCER GAS AMMONIA RECOVERY PLANT

One can easily overrate, too, the importance of saving steam. In the Mond process, practically all the steam is generated from waste heat and, moreover, most of it is continuously recovered. Any further saving can only be secured at the expense of some of the sulphate of ammonia yield. At all events, Mr. Moore states in his published matter that he obtains more ammonia when he introduces more steam, hence his usual amount of steam does not produce the maximum ammonia recovery.

Fig. 10 illustrates a plant built on the Moore system. The small air-cooled tubes are so constructed and in such a position as to bring about great likelihood of frequent stoppage of the plant on account of tar and dust deposits. Whatever may be the results with this plant with non-caking coals, the plant does not seem to be applicable to caking

fuels with any reasonable degree of efficiency. The only publication regarding this system which has come before the writer shows the results of tests of but five hours duration, which tests have obviously but little value for practical purposes.

Some five years ago the writer set out to design a new type of plant which should retain the advantages of previous types without their disadvantages. He was led to do this by the realization that, in spite of the extreme cheapness of producer gas as made by plants operating under the Mond system and although a considerable number of plants had been built and operated in a somewhat re-

stricted number of countries, the adoption of the producer gas process had not become general throughout the industrial world. Careful investigations of the situation led to the conclusion that although the process as such was, and is, really good, the means adopted for carrying it out left much to be desired, especially from the point of view of capital outlay, labor requirement, repair costs and simplicity of operation.

These drawbacks were inherent primarily to the ammonia absorption, gas washing, gas cooling and air saturating elements of the plant. All these operations were heretofore carried out in high and cumbersome towers packed with earthenware ring tiles, or in equally cumbersome horizontal luted dasher washers, both of which the author set out to replace.

FIG. 13 8000 H.P. LYMN SYSTEM PRODUCER GAS AND BY-PRODUCT RECOVERY PLANT

A system of vertical washers, in which an intensive washing of the gases was brought about chiefly by means of the momentum of the gases, was first designed and put into practice. Vertical mechanical washers had not previously been used in gas producer plants and the writer first designed one on the lines already known in other branches of the gas industry, in which the washing liquid was sprayed by means of a series of co-axial revolving discs onto collecting cones, each of which delivered the liquid directly onto the next revolving disc below, and so on. It was found, however, in setting this washer to work, that with such an arrangement, the momentum of the gas was performing

much more work than was the mechanical movement of the discs, a rather surprising fact. Accordingly, the mechanical feature of the washer was eliminated, the collecting cones were cut away to give the gas more play and the washer now had the appearance as shown in Fig. 11. It will be seen that if plumb lines are taken down the inside edges of the collecting cones and down the outside edges of the discs, a considerable space exists between them, which is such in practice that, if no gas is passing, the water entering at the top falls straight down to the bottom.

FIG. 15 MOND PRODUCER COMBINED WITH TALBOT STIRRER

With this modified washer, a plant originally designed to deal with the gas from 45 to 50 tons of coal per day was able to deal with that from 90 to 100 tons per day, so that the capital outlay of the gas washing part of the plant was straightway reduced one half. Such washers have now been in operation for approximately two years with entire success, and it is now possible to design washer units of this particular type to deal with quantities of gas from 10,000 up to about 1,300,000 cu. ft. per hr.

Fig. 12 illustrates the general appearance of a plant with these Lymn washers. The dimensioning of the washers is not a very simple matter, being of necessity purely empirical, and the author has arrived at the dimensions en-

FIG. 14 DUFF PATENT REVOLVABLE PRODUCER

tirely by stepwise trial, which has obviously not been done without considerable expense.

If Fig. 12 is compared with the previously shown diagrams of other plants, it will be seen that the whole apparatus looks much less cumbersome and obviously simpler in operation, involves less auxiliary machinery and consequently less first cost. It will be further noted that in the

FIG. 16. MOND-TRUMP PRODUCER WITH DRY ASH DISCHARGE

Lynn system exactly the same kind of apparatus is employed for each of the operations of absorbing the ammonia, cleaning the gas and recovering the steam. For the final stage of removing the last traces of tar, etc., however, centrifugal cleaners combined with dry scrubbers, or such methods as have been proposed by H. F. Smith, have to be utilized.

One other point to which attention might be drawn is that the Lynn plants do not contain any lead parts, steel being used for the parts of ammonia absorbing apparatus. A Lynn plant constructed with no lead whatever has been in operation in Germany for approximately four years and no corrosion has yet been discovered. This plant is shown in Fig. 13. Its capacity is 8000 h.p.

A second direction in which the author claims to have made considerable improvements is in the removal of dust. These improvements have been accomplished by the adoption of a cyclonic dust separator of somewhat special design.

FIG. 17. A. B. DUFF'S PATENT MECHANICAL STIRRER

With this separator, the bulk of the dust is removed in a dry state and not by means of water, as in other plants. The removal of all the wet and sloppy dust from the earlier horizontal rectangular washers was a very troublesome proceeding, involving considerable costly manual labor, as will easily be realized.

In the gas producer itself, the writer has taken considerable pains to apply to ammonia recovery plants the mechanical action which has been so widely applied to ordinary gas producers, both in the United States and in Germany but not so much in England. This mechanical action involves agitation in the fuel and ash zones of the producer and mechanical ash removal. Many attempts in this direction of mechanical action have previously been made and some of them have met with more or less success. The writer

believes the first of such proposals was made by E. J. Duff, who designed an octagonal-section revolvable producer with a stationary grate, ash trough and top, as shown in Fig. 14. This design was disclosed in British Patent No. 15,646 of 1901, but the specification does not state that it was intended for ammonia recovery purposes, although, as far as the author's recollection goes, the inventor considered it primarily in this connection. The writer is unaware of any practical trial having been made of this producer.

FIG. 18 FIRST SECTION OF A 13,000 H.P. LYMN SYSTEM PRODUCER GAS AND BY-PRODUCT RECOVERY PLANT

FIG. 19 5000 H.P. LYMN SYSTEM PRODUCER GAS AND BY-PRODUCT RECOVERY PLANT DURING ERECTION

The next of these proposals was a combination of the well-known Talbot stirrer with the Mond producer. This was made by Dr. Mond himself and is shown in Fig. 15. This apparatus was tried out thoroughly with various coals of a more or less caking nature. It was very costly to install and its operation was not without difficulties. The writer does not know of any more producers of this type being built beyond the first.

Another attempt to adapt revolving producers to am-

monia recovery plants was one made by the author, but although its trial was much hampered by the fact that the makers failed to build the device to drawings and specifications, it was certainly not sufficiently successful to warrant general adoption. The great depth of fuel requisite for ammonia recovery renders the operation of mechanical producers exceedingly difficult. One of the difficulties found by the writer in practice was that, when using a caking coal, the producer revolved while the coal remained more or less stationary, resulting only in the grinding of the coal at the periphery of the producer.

Another step in this direction was the combination with the producer of the mechanical ash removing apparatus designed by Mr. Trump. This combination is illustrated in Fig. 16 and has been adopted on a somewhat large scale. A battery of these so-called Mond-Trump producers was built in England and at the time of its installation the writer was hopeful that the combination, though very costly, would prove to be a valuable development; however, the in-

FIG. 20 PEAT POWER GAS PLANT WITH AMMONIA RECOVERY AT PONTEDERA, ITALY

formation to hand regarding it is not very encouraging.

Still another proposition is that made by A. B. Duff, in which a mechanically operated stirring poker is utilized in the producer (Fig. 17). This worked very well indeed when tried with Scotch washed nut and the writer believes it has been further adopted for use with this or similar coals. Scotch coal does not cake, however, and therefore with such coal there appears to be insufficient justification for incurring the additional cost of this stirring gear, except it be for the purpose of increasing the rate of gasification. The writer has had a great deal of experience with Scotch nut in stationary producers and has never had the slightest trouble with this coal. He would therefore be interested in the results obtained with this device when applied to English caking coals, and still more to those in this country.

The design of producer adopted in the Lymn plants was based on the principle which has been so largely utilized for ordinary hot gas producers in Europe, where the rotary grate and the mechanical ash removal have been further constructionally improved and very widely introduced both by Kerpely of Vienna and by the writer's German licensees. On the basis of the last-named firm's designs as adopted for hot gas producers, the system has been applied to ammonia recovery, material modifications being of course necessary.

DRIVING LARGE GAS ENGINES AND FIRING FURNACES

NOTE:—The nitrogen efficiency during these two periods was 70 per cent. It is frequently 75 per cent.

These modifications are to provide a vastly increased volume of air and steam, a deeper fuel bed, superheating of the blast of air and steam, increased pressure of the air blast and consequently deeper water lute, etc. Plants on this system have been built by the Badische Anilin und Soda-Fabrik, of Ludwigshafen (Fig. 18), and by the German Government at Heinitz (Fig. 19). Several others are under construction. These represent the latest type of Lynn plant adopted in large scale practice.

The plants in operation have worked well and a resumé of the operating results of one plant is given in Table A. These results are taken from the daily log sheets of a plant now gasifying about 80 tons of coal per 24 hours, the gas being used for driving four 1300 h.p. gas engine electric sets and also for firing furnaces. The coal in use is common slack and brown-coal at an average price of 12 to 13 shillings per ton. The heating value of the coal is 10,400 B.t.u. per

FIG. 21 VALUE OF U. S. IMPORTS AND PRICE FLUCTUATIONS OF AMMONIUM SULPHATE 1900-1913

lb. (6000 kg. cal. per kg.) and the nitrogen contained in the coal averages 0.80 per cent. These records cover two periods of four weeks, each being selected quite haphazard. In spite of the high cost and low nitrogen content of the coal, the cost of gas per kw-hr. worked out at only 0.55 pfg. or 0.13 cents, an interesting result.

There is one point in connection with this industry which I think deserves considerable attention. It is well known that the amount of steam generally used in these plants with normal coal is approximately 2½ tons for every ton of coal gasified. Of this amount, up to two-fifths is recovered from the heat of the gases (i.e., during the gas cooling and air saturating cycle of operations) in a modern and properly designed plant. The remainder, 1½ tons, has, however, to be made by direct coal-fired boilers or other means. Needless to say the provision of separate boilers involves a considerable charge on the operating costs of the plant, and it should therefore always be one's endeavor to obtain as

large a quantity of steam as possible in the form of waste steam at practically atmospheric pressure (which is quite sufficient) or to raise such steam by utilizing waste heat.

In connection with gas power plants, the steam can be made by utilizing the heat of the exhaust gases from the gas engines. This is a problem to which the author has devoted considerable attention, and in the plant referred to above, all the steam is produced in special boilers of his own design which are heated by the exhaust from the gas engines. In this particular installation there are four boilers, each attached to a 1300 h.p. gas engine, and each raising 2 to 3 lb. of steam per h.p.-hr. This amount of steam is 25 per cent more than that required for the gasification of the coal.

FIG. 22 TOTAL PRODUCTION OF AMMONIUM SULPHATE AND CONSUMPTION IN THE UNITED STATES

It may be suggested that when boilers are utilized for this purpose there is danger of corrosion, but four years' full-time operation is sufficient criterion that this is not so. The writer's experience is that satisfactory operation is merely a question of properly dimensioning the boilers.

The above mentioned plant is the first in the world to be absolutely self-contained as far as steam is concerned and great strides are now being made in the Lynn plants in the matter of utilizing the heat of waste gases from all kinds of operations for the production of steam.

It might be of interest here to give some particulars of the largest gas engines, just ordered from Messrs. Ehrhardt and Schmer by the Farbwerke Hoechst, Main, which will be coupled to a Lynn plant consisting of five producers. The three engines are each of 4500 h.p., run at 94 r.p.m., and have only two cylinders, each of 1330 mm (4 ft. 4½ in.) diameter and 1400 mm (4 ft. 7 in.) stroke.

In regard to the utilization of the gas for steam rais-

ing purposes there is a great deal to be said, but it will merely be mentioned that the efficiencies which may be realized in well-constructed plants are from 70 per cent upwards (indeed in the Bone system efficiencies of 90 per cent or more have been actually achieved in the writer's presence). Considerable development in this direction of high efficiencies of gas-fired boilers is looked forward to, and the writer has applied in most countries for patents on a different system for achieving similar results to Bone.

At all events, it is important to realize that where coal is expensive gas engines are obviously the more economical to adopt, and where coal is cheap the by-products more than pay for the coal and the gas can be made for nothing or even at a profit. In the latter case, it does not matter very much what quantities of gas are used per h.p., and under such circumstances gas-fired steam plants become as profitable as gas engine plants or more so.

To give a general idea of the adaptability of ammonia recovery plants for power as well as for heating purposes, three estimates of working costs have been made for (I) a 2000 h.p. power gas installation, coupled together with gas engines and working 4000 hr. per annum, (II) a 4500 k.w. producer gas plant, coupled together with gas engines and dynamos furnishing current for say electrochemical purposes, working 8500 hr. per annum, and erected near a colliery where the coal will be cheap, and (III) a producer gas plant for a daily and continuous gasification of 500 tons of coal, the gas being used say for firing steel furnaces. The estimates are given in Table B. The working costs of these three plants are based upon the actual results in practice referred to above. It has been assumed that the cost of labor is 50 per cent and the cost of apparatus is 25 per cent more than in England and Germany.

It will be realized that for industries such as electrochemical plants requiring a large amount of power, it is quite unnecessary to have recourse to water powers which are almost invariably situated in localities quite unsuitable as manufacturing sites and which therefore require long, costly and unreliable transmission systems subject to the dangers of sleet, wind and electrical failures. Every power user who depends upon an uninterrupted supply of current for the success of his operations would gladly dispense with this transmission, even were its high cost of no importance.

In considering the development of ammonia recovery plants, the statements made so far have referred to the treatment of coal, which is obviously the most used combustible. They may also be taken, however, as applying to waste coal containing a high percentage of ash, as well as to other poor grade coals, such as lignite, coke breeze, etc.

Coke breeze, as obtained in the manufacture of lighting gas, has now a particularly advantageous application in these plants. It is well known that as a general rule the retorts in gas works are heated by means of good trade coke which has a high selling value, but the coke breeze which is sieved out is practically a waste product. This substance can now be dealt with, producing all the gas for firing the retorts together with about 60 lb. (value \$1.20) of sulphate of ammonia per ton of breeze. Furthermore, much good coke is thus set free for sale to the public at a high value. A large plant is already operating on these lines in England and is very successful and profitable.

There are, however, other combustibles whose use in producer plants is restricted on account of the high percentage

of water they contain. Such in particular are peat and wet brown-coal.

The writer, as technical manager to The Power-Gas Corporation was able to apply successfully the Mond Gas process to the treatment of peat between 1904 and 1907. The drying of peat is a most difficult matter and in view of this fact it is interesting to note that today it is possible to produce regularly power gas and by-products from peat containing up to 60 per cent water. This peat can be obtained by relatively short periods of drying in the atmosphere in

practically all countries. Evidences of success in this matter are the facts that a 20-ton plant was erected in Germany, some years ago to demonstrate the advantages of this process, and another plant (Fig. 20) dealing with 100 tons of peat per day and producing sulphate of ammonia and power gas has been in operation in Northern Italy for about three years. In the latter case a further peat bog has now been purchased and a second and larger plant built upon it. The writer, too, has entered into a contract for building in Russia a plant of this type to treat 90 tons of peat (stated as theoretically dry) per 24 hr.

The quantity of ammonium sulphate produced per ton of peat depends upon the nitrogen content and varies between 70 and 220 lb. per ton of dry peat gasified. Where peat with about 2 per cent nitrogen is available, one can obtain a large profit simply from the ammonium sulphate, regarding the gases as a by-product. Indeed, with peat which contains

little nitrogen, gas can in most cases be produced without cost. Other by-products which can be produced from peat are tar (which contains much paraffin), also acetate of lime, etc.

The application of the Mond process to peat as worked out in England has at times been erroneously referred to as the Frank-Caro process. As a matter of fact, however, only one plant was built according to Frank and Caro's designs. This was at Osnabruck, Germany, and it was shut down after twelve months' operation.

In conclusion, the By-Product Producer Gas industry has not been exploited to the same extent in the United States as in Europe, and one object of this paper has been to bring before the engineers of this country the facts relating to an established industry the great advantages of which are at their disposal. These advantages are well recognized in Europe and in other parts of the world and it seems almost an irony of fate that the United States has benefited so little from them.

The author's long experience in Great Britain, Germany and other countries with many kinds of fuel, from peat to brown-coal and from anthracite to the most bituminous coals, does not, however, lead him to dogmatize upon the utilization of the vast range of fuels in this country in plants which have so far been used almost entirely elsewhere. Indeed he is well aware that mistakes have been made in this country in the past by adopting *en bloc* European designs. It might be of interest to know that a plant of his design already modified to suit the local conditions is now being extensively experimented with at an important colliery in the Pittsburgh region and trials on a large scale of all qualities of coals, from waste roof coal upwards, are now being very thoroughly carried out in a Lynn Plant under the direction of Lewis A. Riley, 2d, member of the Society.

About fifty By-Product Producer Gas Plants are already built having a yearly fuel capacity of approximately 2,000,000 tons. These are distributed among Great Britain (which has most of them), Germany, Italy, Spain, China, Japan and this country. The total yearly fuel capacity of them all is close upon two million tons. The gas from them is being used not only for power production but also for all kinds of industrial heating operations, such as reheating furnaces, forging furnaces, annealing furnaces, steel furnaces, core stoves, crucible heating, galvanizing baths, gas works retort firing, spelter furnaces, glass works operations, evaporating brine, calcining operations, roasting

operations, distilling operations, heating drying rooms, etc.

It may be contended by many that the adoption of a large number of ammonia recovery plants would run down the sulphate of ammonia market, but it must be borne in mind that in England, where by-product producer gas plants have made more progress than in all other countries together, the proportion of sulphate of ammonia made by this means amounts to only 13 per cent. The remainder comes from lighting gas plants and coke ovens which in Germany, and also to a great extent in England, are producing nearly as much sulphate of ammonia as is possible.

The consumption of sulphate of ammonia is steadily on the increase, although the market has fluctuated considerably during the past year. This substance must therefore be supplied from other sources than those which have so largely supplied it up to now. The author has personally considered this question somewhat closely with reference to the production of nitrogenous fertilizers and is convinced that there is room for a very large increase in the production of sulphate of ammonia from gas producer plants, in spite of the increasing production of synthetic nitrogenous fertilizers.

In this connection Figs. 21 and 22, showing the imports and price fluctuations as well as the comparative production of ammonium sulphate in this country over the period from 1900 to 1913, might be of interest. In considering these data it should be borne in mind that the quantities represented form only a part of the whole nitrogenous fertilizer trade, which comprises, in addition to ammonium sulphate, nitrate of soda, calcium cyanamide, nitrate of lime, guano and animal waste generally.

Regarding the nitrogen content of American coals, Table C represents the average of some 1500 analyses made by that thorough body of workers, the Department of Mines of the U. S. Geological Survey. More than 560 million tons of coal per annum, containing on an average about 1.3 per cent nitrogen, are produced in this country. Imagine this quantity of coal being converted into producer gas and the ammonia recovered from the whole of it, and deduct the amount of sulphate of ammonia which is already produced. The remarkable result is arrived at that about 25 million tons of sulphate of ammonia, having a value of 600 million dollars, are wasted per annum. Surely it is worth while to consider recovering at all events a small portion of this, especially when it is realized that every dollar spent by agriculturists in sulphate of ammonia means crops.

MODERN STEELS AND THEIR HEAT TREATMENT

BY ROBERT R. ABBOTT,¹ CLEVELAND, OHIO.

Non-Member.

STEEL is an alloy. In its most simple form it is made up of two components: iron and a carbide of iron technically known as cementite. Commercial steel always has at least four other elements present: phosphorus, sulphur, manganese, and silicon, but the total amount of these four elements contained in an ordinary commercial steel is less than 1 per cent, and the influence of the average variation in all of these impurities upon the physical properties of the steel, is slight compared with the effect of the carbon.

The carbon is the main factor in influencing variations in the physical properties. It varies from practically nothing in wrought iron to about 1½ per cent in high carbon tool steel. A variation of 0.1 of 1 per cent of carbon will affect the tensile strength of annealed steel about 8000 lb. per sq. in. The carbon exists as cementite, which is fifteen times as heavy as the carbon of which it is composed. In steel this cementite occurs intimately mixed with about 6½ times its own weight of iron. One part of carbon, therefore, makes up about 112½ parts of this mixture, which is known as pearlite. A steel containing 0.1 per cent carbon is really composed of about 11 per cent pearlite and 89 per cent of iron.

A sample of iron, magnified to 150 diameters, shows about 0.01 per cent carbon, which makes the structure 1 per cent pearlite and 99 per cent iron. This pearlite is not visible under this magnification, and, therefore, the material has the appearance of pure iron. As the carbon increases the pearlite areas become larger and the amount of iron smaller. A microscopic photograph of a steel containing 0.20 per cent carbon shows about 22 per cent pearlite.

Another sample with a still further increase in carbon to 0.40 per cent shows 45 per cent pearlite and 55 per cent iron. Similarly, an 0.80 per cent carbon steel, contains 90 per cent pearlite and 10 per cent iron, while in a 0.90 per cent carbon there is no excess iron and, therefore, 100 per cent pearlite.

As the carbon increases above the point necessary to form 100 per cent pearlite it must necessarily exist as free cementite, as all the iron has been taken up to form pearlite when the carbon reached 0.90 per cent.

A steel with 1.4 per cent carbon, consists of 92.5 per cent pearlite and 7.5 per cent cementite. A steel containing 2.5 per cent carbon, consists of 24 per cent cementite and 76 per cent pearlite. A steel of this high carbon is rare and has no commercial application. White cast iron, which is the material from which malleable iron is made, is an impure steel of a carbon content similar to this.

Briefly summarizing the structural condition of a series of steels of various carbon contents, we see that one con-

taining 0.9 per cent carbon consists of 100 per cent pearlite. This steel is known as saturated, or, commonly, an eutectoid, steel. A steel containing less than 0.9 per cent carbon contains pearlite and iron. It is known as an undersaturated or hypo-eutectoid steel. A steel with more than 0.9 per cent carbon is known as super-saturated or hyper-eutectoid steel; it contains pearlite and cementite.

When a piece of steel is pulled apart in a tensile machine the cross-sectional area at the point of fracture is less than that of the original bar. The amount of this difference is known as the "reduction in area," and it is a fair measure of the toughness of the steel. While the meaning of the term "toughness" is open to more or less dispute, we can consider it as the ability of the metal to distort without causing fracture. For example, a steel which can be bent through an angle of 75 deg. before fracture is tougher than one which can be bent only 25 deg.

If tensile tests are made on a series of steels of increasing carbon contents we find that the tensile strength increases with the increase in the amount of pearlite, but the toughness decreases.

The tensile strength of iron is about 40,000 lb. per sq. in. This can be increased by about 700 lb. for each increase of 1 per cent pearlite. The reduction in area for pure iron is about 80 per cent and this is decreased by about 0.5 per cent for each increase of 1 per cent pearlite. For ordinary structural purposes a steel which is subject to vibration or shock is not safe with much less than 50 per cent reduction in area. From these figures it is readily calculated that a steel with 60 per cent pearlite, which corresponds to about 0.55 per cent carbon, has a reduction in area of about 50 per cent. Such a steel has a strength of approximately 80,000 lb. per sq. in.

Evidently, then, the strength of a steel subjected to dynamic stresses can be safely increased up to 80,000 lb. per sq. in. by the use of an increased carbon content; however, every additional increase in strength is obtained at the expense of the toughness. A further consideration is the fact that the hardness of the steel, and therefore the difficulty and expense of machining, increases with the pearlite.

A little consideration of the above facts will show that they are logical and what should be expected. The pearlite is composed of fine plates of pure iron strengthened and made rigid by cementite, which itself is intensely hard and strong, but very brittle.

The pearlite, as a mass is strong, but, due to the cementite in it, it is not as tough as pure iron. Pure iron compared to pearlite is weak but tough. A combination of the two will give characteristics consistent with the proportion of the constituents.

It is apparent that in order to obtain greater strength on the steel without increasing the amount of pearlite, or, what is the same thing, the amount of carbon, at least three things can be done: (1) increase the strength of the iron, (2) increase the strength of the pearlite, or (3) increase the strength of both. Practically, these are reduced

¹ The Peerless Motor Car Company.

Abstract of paper presented at a joint meeting of the Philadelphia local section of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS and the Franklin Institute on January 14, 1915. This paper was published in full in the Journal of the Franklin Institute, April, 1915, to whom we are indebted for the use of the illustrations.

to two, because anything which increases the strength of the iron also increases the strength of the pearlite to some extent, because of the iron in it.

This can be accomplished by adding to the steel some element or elements which will alloy with either the iron, the pearlite, or both, and increase their strength. A steel containing this extra element is known as an alloy steel. There are two classes of alloy steels: those in which one or more of the normal impurities are made abnormally large, and those in which one or more elements not normally present are added. To the first class belong silicon and manganese steels. To the second class, which is the more important commercially, belong nickel, chrome, chrome vanadium, chrome nickel, tungsten, and titanium steels.

As typical examples of the two methods of increasing the strength of steel, nickel and chrome steels may be considered. Nickel forms a solution or alloy with the iron

FIG. 1. STRUCTURE SHOWING CEMENTITE AND PEARLITE, 1.4 PER CENT CARBON (150 DIAMETERS)

which is stronger than iron alone. Chromium replaces some of the iron of cementite, forming a carbide of chromium. The pearlite thus formed from the double carbide of chromium and iron is stronger and at the same time tougher than ordinary pearlite formed without chromium. The most widely used nickel steel contains 3½ per cent nickel, while the common chrome steel has about 1 per cent chrome. Such a nickel steel will be about 20,000 lb. per sq. in. and chrome steel about 15,000 lb. stronger than a simple steel of the same carbon content. At the same time the toughness of the nickel steel will be about the same as that of a simple steel, while for the chrome steel it will be a little greater. It is apparent, then, that the use of an alloying element to increase the strength of steel is better than to use carbon for the same purpose, as the increased strength is not obtained at the expense of the toughness.

Thus the relation between strength and toughness in ordinary steel can be varied by changing the relative amounts, and also the strength or toughness of two substances composing it; namely, the pearlite and iron. In either case

this must be done by adding something to the steel: in the first case, carbon, and, in the second, some alloying element. Can we not change the relative amounts of the elements or their strength by some process of heating?

Consider the steel containing 0.20 per cent carbon, which forms about 22 per cent pearlite. If we heat this to a temperature of 1000 deg. Fahr. and suddenly cool or quench it in cold water, it will be found that neither its physical properties nor its appearance under the microscope has been changed; if the temperature is increased to 1100 deg., still no change is found; nor will any difference be detected until a temperature of about 1375 deg. Fahr. is reached, when it will be found that the iron is still present and in about the same amount, but the pearlite areas have become more or less rounded. If examined under 1200 diameters, it will be found that the white areas are the iron, while the dark areas represent what was originally pearlite; it has now apparently coalesced, so that the original cementite and ferrite of which it was composed have merged into a single substance.

The real explanation of the change which has taken place is that the iron which originally composed part of the pearlite underwent an allotropic change at this temperature, and in its new form it is capable of dissolving to a solid solution the cementite with which it was in contact. This new solid solution is known as austenite, and by the sudden quenching, time is not given for the reverse allotropic change to occur completely. It cannot be entirely prevented, and the transition substance which we really obtain is known as martensite.

A steel thus treated is different from the untreated steel in one of its constituents, and is made up of iron and martensite instead of iron and pearlite. Martensite is much stronger but more brittle than pearlite. We should then expect that our treated steel should be stronger but less tough than the one not treated. The untreated steel has a tensile strength of about 55,000 lb. per sq. in., and a reduction in area of 65 per cent. The same steel heat treated as just explained has a tensile strength of about 95,000 lb. per sq. in., and a reduction in area of about 30 per cent. These properties are very similar to those of a high carbon steel containing about 100 per cent pearlite or 0.90 per cent carbon. In other words, by a simple process of heat treatment, we can obtain with a 0.20 per cent carbon steel the physical strength of a 0.90 per cent carbon untreated steel.

If at some definite temperature the pure iron in the pearlite went into a solid solution with the cementite, possibly at a still higher temperature, more of the iron could be caused to go into such a solution. A photograph of the structure of the same steel quenched from 1440 deg. will show that the iron has decreased in amount, while the martensite has increased. Apparently then, as the temperature is raised, the saturation point of the martensite for iron is increased; just as in a water solution more sugar can be caused to dissolve by increasing the temperature.

At a temperature of 1565 deg., all of the iron will go into solution and the quenched steel will consist of 100 per cent martensite. A high magnification (1200 diameters), shows the martensite structure to be triangular. Thus, it is seen that as the steel is subjected to an increasing temperature of quenching, the amount of iron constantly decreases until

it becomes zero, while with the increase of carbon, the pearlite increases to 100 per cent and with the increase of temperature, the martensite increases to 100 per cent.

With the increase of temperature, the strength increases, beginning with the temperature of the first change, until final absorption of the iron, while the toughness also increases if the carbon is low. Table 1 illustrates this more fully:

TABLE 1. VARIATIONS IN STRENGTH AND TOUGHNESS IN UNTREATED AND HEAT-TREATED STEELS

Untreated steel			Heat-treated steel, 0.20 per cent carbon		
Per cent pearlite	Strength	Toughness	Per cent martensite	Strength	Toughness
25	55,000	65	25	95,000	30
50	75,000	55	50	98,000	40
75	90,000	45	75	100,000	50
100	105,000	35	100	105,000	55

The temperature at which the pearlite first changes is known as the lower critical temperature, and the temperature at which the absorption of iron is complete is known as the upper critical temperature. It is apparent that of two steels containing different percentages of carbon, and therefore different percentages of pearlite, the one containing the more pearlite will have less iron to dissolve, and therefore the temperature of final absorption will be lower. In other words, the upper critical temperature is lowered by an increase in the carbon content. If the steel is all pearlite, *i.e.*, contains 0.90 per cent carbon, its upper and lower critical temperatures will coincide.

With some steels the best results are obtained by quenching just at the absorption point, while with others a higher temperature is necessary. The metallurgist must know the amount of this variation for different types of steels.

The heat treatment of an alloy steel is exactly the same in principle as that explained above for plain carbon steels, the alloying elements giving increased strength as well as increased toughness to the heat treated, in the same manner as it did in the untreated steel.

From the foregoing, it is apparent that a steel heat-treated to bring out high strength, will consist of 100 per cent martensite, no matter what amount of carbon there was originally present, or whether alloying elements were there or not. Evidently then, martensite will have a varying composition. Under the microscope there is very little difference in appearance, no matter what the composition. Since martensite is really formed from a solution of cementite in iron, a high-carbon steel will form a stronger solution than a low-carbon one, just as a strong or weak solution of salt can be had in water. Alloying elements in the martensite do not cause any difference in its structure any more than a little sugar would cause a difference in the appearance of a salt-water solution. These alloying elements, however, have a very decided influence upon the position of the critical temperature; for example, 0.1 per cent manganese lowers the upper critical temperature 6 deg., while it has practically no effect upon the lower critical temperature; 0.1 per cent chromium raises the lower critical temperature 4 deg. when nickel is absent, but with nickel present it raises it only 3 deg., but in neither case does it have any appreciable in-

fluence upon the upper critical temperature. The business of the metallurgical engineer is to know absolutely the influence of all elements upon these critical temperatures.

In general, these martensites made from a steel containing more than 0.2 per cent carbon have not enough toughness for their strength, and to remedy this, the steel is given a second low heat, commercially known as a drawing heat, which allows a certain amount of transformation to take place in the martensite, and reduces its strength but increases its toughness. By varying the final heat, an unlimited number of combinations of strength and toughness are available. As the drawing temperature is raised still higher the micro-structure of the steel becomes extremely fine and it is known as sorbite. This is really an imperfect pearlite intimately mixed with iron.

Broadly summarized, the process of heat treatment consists in transforming an alloy from a mechanical mixture of two substances into a homogeneous solution of a single sub-

FIG. 2 STRUCTURE SHOWING CEMENTITE NEEDLES (350 DIAMETERS)

stance. This very fact gives to a heat-treated steel one of its most valuable advantages over the untreated steel; namely, its ability to withstand repeated shocks or vibrations, or, as it is popularly expressed, "fatigue-resisting power." The reason is obvious: an alloy composed of two dissimilar substances has mechanical boundaries between them. This fact is a source of weakness under repeated stresses, the reasons for which are more or less complicated. An untreated steel contains these boundaries; a correctly heat-treated steel does not.

There is a still further advantage based upon a different consideration. A steel with a tensile strength of, say, 60,000 lb. per sq. in., if subjected to repeated reversals of stress of any magnitude, will finally break after a definite number of these reversals; as the magnitude of these stresses approaches the actual strength of the steel, the number of reversals necessary to cause a break rapidly decreases; as a consequence of this fact, a comparatively slight increase in the strength of a piece of steel will increase way out of proportion its resistance to fatigue break. Therefore, it is frequently desirable to heat-treat a piece of steel to give it

an added factor of safety under shock or alternate stresses, even though its static factor of safety is sample.

In supersaturated steels,—that is, those containing more than 0.90 per cent carbon, we have present cementite and pearlite. Most tool steels belong to this class. In the heat treatment of such a steel, the pearlite changes to austenite at the same temperature which we found for an under-saturated steel. As the temperature is raised above this point, the excess cementite begins dissolving into this austenite, just as the iron did in a lower carbon steel, until at a definite temperature all of it is dissolved, and we have, as before, austenite. The cementite is more sluggish in dis-

solving into the austenite than the iron, and the reaction requires more time to complete. As we have previously seen, cementite is extremely brittle and hard; it occurs usually as sheets in the pearlite or thin envelopes surrounding grains of pearlite. These two types are shown in Fig. 1 (150 diameters) and Fig. 2 (350 diameters). A piece of tool steel which has been previously slowly cooled from above the temperature at which the last of the cementite went into solution will contain the cementite in one of these two forms. If it is hardened at the lowest possible temperature its pearlite will be changed to martensite, while its cementite will be unchanged. These sheets or envelopes of cementite will cause the steel to be extremely brittle, and is a source of many of the troubles of the steel user.

Now if the steel is quenched from above the upper absorption point this cementite will be gotten rid of, but the steel is somewhat softer because of its absence. The structure of the steel has also been coarsened by the high temperature, which causes it to be brittle. If the coarsened steel is again reheated slightly above the lowest hardening temperature, the cementite will be precipitated out of the solution, but, instead of being in sheets or plates, it will occur as fine dots, which give extremely good wear and have practically no effect of brittleness. A steel thus treated is shown in Fig. 3 (350 diameters). This same arrangement of cementite can be formed by heating the steel to just above

the lowest hardening temperature and holding at this temperature for some time.

In an alloy steel the influence of carbon is reduced, and this reduction is greater the higher the percentage of alloy. For structural purposes the carbon of alloy steels rarely exceeds 0.50 per cent; those containing less than 0.25 per cent are usually used for parts which are to be surface-hardened by the carbonizing process, and above 0.25 per cent for parts which are to be subjected to stresses which do not require a hardened surface.

In the carbonizing process the outer surface of a low-carbon steel has its carbon content raised by heating in contact with carbonaceous material. The depth of penetration of this high-carbon shell and also the percentage of carbon it contains are functions of the carbonizing material used and the temperature and time of carbonization in general; the outer surface should be a supersaturated steel, and therefore its treatment comes under that of tool steel, which we have just considered.

To produce a correctly heat-treated, carbonized article we have four functions to consider: (1) the chemical analysis of the steel; (2) the carbonizing material; (3) the time of carbonization, and (4) the temperature of carbonization. These should be adjusted so that the upper absorption point of the iron of the core shall exceed that of the cementite of

FIG. 3. STRUCTURE SHOWING CEMENTITE GLOBULES (350 DIAMETERS)

FIG. 4. CORE OF CARBONIZED STEEL, SINGLE QUENCH (150 DIAMETERS)

the case. Under these conditions, if the steel is quenched from above the absorption point of the core, this will be entirely martensitic, and at the same time the cementite sheet or net of the case will be absorbed, so that it will also be martensitic.

Now in order to obtain the maximum hardness on the surface this cementite must be precipitated, as shown in Fig. 3, by a low quench from the hardening temperature. During this second quench the iron of the core will also be precipitated out in practically the same globular form, with this difference: there being more excess iron than excess cementite in the core, the iron will precipitate in larger particles and will not have the characteristic globular appearance.

A comparison of the difference in structure of the core of a piece of carbonized steel with a single hardening heat and this double refining and hardening heat is shown in Figs. 4 and 5. In both cases we have the same amount of martensite (black) and iron (white) present, but the mixture is much more intimate and fine in Fig. 5 (double quench). This increases enormously the toughness of the finished steel.

DISCUSSION

H. V. WILLE. The theory of heat treatment has been understood by metallurgists for many years, but this has been largely applied in a practical way only during recent years. Some years ago Dr. Sargeant, who is now connected with the Crucible Steel Company of America, exhibited a small experiment at the Franklin Institute which showed in an interesting way the basis of all heat treatment of steel. He heated in a flame of a Bunsen burner a thin plate until he obtained a red spot. Upon removal from the flame he showed that this spot gradually decreased in brightness until a certain temperature was reached, whereupon the fall of the temperature was arrested and the spot glowed with a marked increase in luminosity, showing that some internal change had taken place in the molecular structure in the steel which caused the elevation in temperature in a manner similar to that produced by the combination of sulphuric acid and water.

If the steel is quenched at this temperature, it will retain its molecular structure, and if examined it will be found that steel so quenched is of maximum hardness, with a less loss of ductility for that particular grade. Furthermore, the molecular structure will not be changed unless the steel is again heated above this critical or recalcense point. It follows therefore that a steel so quenched can be annealed below this temperature without change in the molecular structure, but with a great increase in ductility. A steel so treated has a much higher elastic limit and a much greater reduction of area than steel which has been subject to the ordinary annealing process. The sole advantage of all of the modern high-grade steel consists solely in an increase in the elastic limit, so that the designer is enabled to reduce the weight or size of any detail by the use of a higher unit stress, or to increase the factor of safety by the retention of the same unit stress as in a straight annealed steel.

Extremely high elastic limits can be obtained by the use of the various alloys to assist the hardening effect of carbon, such as nickel and chromium, or of the various tertiary alloys, such as chrome nickel, chrome vanadium, or chrome titanium. Steel can be produced having an elastic limit of 150,000 lb. with sufficient ductility to prevent failure by shock by the use of some of these alloys with proper heat treatment, so that engineers are able to design parts with unit stress as high as 100,000 lb. per sq. in. in place of about 20,000 lb. per sq. in. for a straight carbon annealed steel. It is hard to grasp the great benefits derived from this enormous increase in the elastic limit.

I do not, however, feel that the possibilities of the use of straight carbon, heat-treated steel have been utilized to the fullest extent. This condition results from the fact that metallurgists write the specifications to which steel is

purchased, and the chief object of the metallurgist is to secure a steel of maximum ductility. The designing engineer, however, is not concerned about the ductility of the steel, but desires a steel having a maximum elastic limit; the manufacturer is unable to produce this steel for the designer because of the ductility requirements in the specification.

Mr. James E. Howard made extensive experiments on tests on rotating shafts. These results showed that the high-carbon, heat-treated steel withstood as many rotations as the more ductile alloy steel, so that it would appear that equally good results could be obtained by the use of the cheaper high-carbon, heat-treated steel as is obtained from the use of the more expensive and more ductile alloy steel. These views seem to be borne out both by the experience of automobile builders and of the railroads. I recall going through the principal automobile factories in France, about

FIG. 5 CORE OF CARBONIZED STEEL, DOUBLE QUENCH (150 DIAMETERS)

ten years ago, and was shown with a great deal of pride such parts as axles, steering gears, etc., which were bent double because they were made from a very low carbon ductile steel, but the experience of a few years demonstrated an inordinate number of failures from this grade of steel, and the automobile builders then went to the extreme of using the extremely high grade alloy steel, which gave better results, notwithstanding the fact that it possessed less ductility than the carbon steel.

The railroads met with the same experience, and the first experiments in the use of steel in substitution for iron were made with low-carbon steel having the same physical properties as wrought iron. A large number of failures followed this substitution, but they were eliminated by the use of steel having a tensile strength of about 80,000 lb. per sq. in. This grade of steel is successfully used in railroad service, and there is a gradual tendency to go to steel of even higher carbon having a tensile strength of about 110,000 lb. per sq. in. Such steels have been used in an experimental way and have fully proved their value in comparison with the higher-priced alloy steels having greater ductility.

A PROPOSED SYSTEM OF CLASSIFYING AND DIGESTING THE RECORDS OF THE SOCIETY

BY EDWIN J. PRINDLE, NEW YORK CITY

Member of the Society

THE records of the Society contain most valuable information upon every branch of mechanical engineering. They present the results of long experience and deep research of many of the most eminent mechanical engineers in the world. And yet I venture that after a paper has passed from the memory of those who heard it or read it, and the volume of Transactions or number of The Journal in which it appeared has ceased to be current, it has practically ceased to exist so far as usefully serving the Society.

Suppose, for instance, an engineer is at work upon some problem involving a detail of boiler practice. There are probably one or more articles upon the general subject of boiler practice in every one of the thirty-five volumes of Transactions of the Society. His detail of boiler practice may have been treated from several points of view, and if he could readily turn to the volume and page where each particular view of his subject is to be found, he might be led immediately to the solution of the problem. The only way, however, in which he can make certain whether or not his topic has been treated in the records is to go over patiently every page of every paper dealing with boiler practice and the entire discussion of each of these papers, and when he has finished, he may find as a reward for his labors, that the point has never been presented. The extent of the labor and the uncertainty of the result will often cause him not to search the records of the Society at all, but to try to solve the problem himself in the hope that he may reach a solution in less time than the perhaps fruitless search would take.

Clearly, any plan which would enable one to turn immediately to all the information which the Society's records contain upon a particular branch or point of a general subject, would be of the greatest advantage to the practicing engineer, and would save from comparative oblivion the fruits of much brilliant and arduous labor represented in papers in the past Transactions and Journals of the Society.

My suggestion to the Society, consists essentially in adapting to its records, methods of classifying, indexing and digesting, with which I have come in contact in the practice of the law, aided in its application to the records of this Society by the experience of the United States Patent Office in classifying inventions in general, and particularly mechanical inventions.

Until comparatively recent years the "Digests" of volumes of legal decisions have been published in book form, and I here present a portion of the index of such a Digest, under the title "Patents" (Fig. 1).

In order to illustrate the advantage of a system which will bring together the reasoning of several articles on the same general subject, I will show how this particular section of the digest is used. We will suppose that in a patent

suit the question arises whether or not the thing shown in the patent amounts to an invention and the bearing on that question of the fact that the sales of the patented article have been large. The point is one which may have

PATENTS

I. SUBJECTS OF PATENTS.

- § 1. Nature of patent rights.
- § 4. Arts.
- § 6. — Principles or laws of nature.
- § 7. — Process or methods.
- § 15. Designs.

II. PATENTABILITY.

(A) *Invention.*

- § 16. Nature of patentable invention.
- § 17. Nature and degree of skill involved.
- § 19. Enlargement or change in degree.
- § 20. Change of form.
- § 21. Substitution of materials.
- § 22. Substitution of mechanical equivalents.
- § 25. Aggregation.
- § 26. Combination.
- § 27. Application to new use.
- § 28. Designs.
- § 29. Reduction to practical use or operation.
- § 31. Evidence of invention.
- § 32. — Presumptions and burden of proof.
- § 35. — Utility and extent of use.
- § 36. — Weight and sufficiency.

(B) *Novelty.*

- § 37. Nature of patentable novelty.
- § 41. New Combination.
- § 42. Production of new or improved result.
- § 44. Knowledge of inventor.
- § 45. Evidence of novelty.

(C) *Utility.*

- § 49. Evidence of utility.

(D) *Anticipation.*

- § 50. Prior knowledge or use.
- § 51. — Nature and extent in general.
- § 52. — Accidental or unintentional production.
- § 53. — Experiments and incomplete inventions.
- § 54. — Unsuccessful and abandoned devices.
- § 56. — Different use or purpose.
- § 57. Evidence of prior knowledge or use.
- § 58. — Presumptions and burden of proof.
- § 59. — Admissibility in general.
- § 61. — Applications for patents.
- § 62. — Weight and sufficiency.
- § 63. Prior patents.
- § 64. — Requisites and validity in general.
- § 66. Operation and effect.
- § 72. Identity of invention.
- § 73. Priority of anticipation to date of invention.

(E) *Prior Public Use or Sale.*

- § 75. What constitutes public use.
- § 78. Priority and continuance of use or sale.
- § 80. Operation and effect.
- § 81. Evidence of use or sale.

(F) *Abandonment.*

- § 82. What constitutes abandonment in general.
- § 83. Delay in making or prosecuting application for patent.
- § 87. Evidence of abandonment.

III. PERSONS ENTITLED TO PATENTS.

- § 90. Original inventors and priority between inventors.
- § 91. Evidence as to originality and priority.
- § 92. Joint inventors.
- § 95. Employers and workmen.

FIG. 1. PORTION OF TYPICAL INDEX OF A LAW DIGEST

been treated in any one of over five hundred volumes of decisions of the Federal Courts. In eight volumes, the digest from which I have reproduced the index on "Patents" covers all Federal decisions upon all subjects since 1880, which occupy three hundred and twenty-five volumes. The subject of "PATENTS" which is treated in about ten per cent of the decisions, is all found in a single volume of this

Digest. Looking at our index of the subject of "PATENTS," the question is one relating to the general subject of the "patentability" of the invention, and to the sub-division thereof of "invention," and it relates to the particular phase of "invention," Evidence of Invention, Sec. 35, Utility and Extent of Use, thus:

"Patentability
Invention
Evidence of Invention
Utility and Extent of Use."

We therefore need to look at Sec. 35 of the subject of "PATENTS." Turning to Sec. 35, we find that it appears as shown in Fig. 2.

Here we find the rulings of four separate courts on cases where the question had been raised whether the thing disclosed in the patent amounted to an invention. The decisions of the Courts (like the papers of our Society) usually contain at least a number of points or subdivisions, each of which may be separately important in the consideration of some particular matter, and therefore each of which points should be the subject of a separate paragraph or

§ 35. — Utility and extent of use.

See 38 Cent. Dig. Pat. § 35.

[a]. (U. S. C. C. A., N. Y., 1909)

While commercial success of a patented device may be important on the question of invention and may determine such question, it is not alone sufficient evidence of mental conception, amounting to invention.—(C. C.) *Fernald v. Onida Nat. Chuck Co.*, 167 F. 559, decree affirmed *Fernald v. Onida Nat. Chuck Co.*, 174 F. 1020, 98 C. C. A. 634.

[b]. (U. S. C. C. A., Ohio, 1909)

The fact that a patented device overcame defects in prior structures which persons skilled in the art had for several years been trying unsuccessfully to remedy, and went into immediate and successful commercial use, is persuasive evidence of invention.—*Electric Controller & Supply Co. v. Westinghouse Electric & Mfg. Co.*, 171 F. 82, 96 C. C. A. 187.

[c]. (U. S. C. C. A., N. Y., 1908)

The fact that the product of a machine made by a new combination of old elements goes into general use and displaces others is some evidence, of greater or less weight, that the new combination involved invention.—*Stafford v. Morris*, 161 F. 113.

[d]. (U. S. C. C. A., Wis., 1910)

The great commercial success of a patented device may turn the scale on the question of invention in a doubtful case.—*Beckwith v. Malleable Iron Range Co.*, 174 F. 1001.

FIG. 2 TYPICAL SECTION OF A LAW DIGEST

syllabus, so that each syllabus can appear in its proper place in the classification of the digest. It would be of interest, therefore, to see how one of the decisions we have been considering is digested.

In Figs. 3 and 3a, are shown the syllabi appearing at the head of the text of the last decision of the group of four we have been considering.

It will be noticed that in the parenthesis in the first line of each syllabus is given the number of the section of the digest in which the syllabus belongs, so that one can readily turn to all other decisions upon the same point, in subsequent volumes of the digest, by looking under the section number. Some digests not only furnish this information, but indicate the page of the decision upon which the point can be found to which the syllabus relates. Decisions are sometimes many pages long, and this device enables one to turn immediately to the part of the decision in which he is interested instead of having to hunt through the entire decision.

This system of indexing and digesting law books is very satisfactory when carefully carried out, except that new vol-

umes of digests have to be published from time to time, as new volumes of decisions are issued (which is constantly being done). This requires either a republishing of the digest to combine several volumes in one, or the consultation of each of the several volumes. Of recent years, a digest covering all the decisions relating to "patents" has been published in card index form, which obviates the difficulties just mentioned as it can be constantly brought up to date by the insertion of new cards.

BECKWITH V. MALLEABLE IRON RANGE CO.

1001

Thus far the process of the patent has been treated as requiring the use of a pinch-cock to close the connection between the lamp and the air pump. The claims are, however, broader than the specifications and drawings, and it is contended that they cover a process wherein the connection is closed by any apparatus which does not necessitate the use of heat. Closure without heat is said to be the process of the present patent; closure with heat, the Maglinani process.

But closure was the essential thing of the Maglinani process. Heat was a mere incident. This incident proved troublesome. What was to be done? As already indicated, I think that mechanical skill should have been quite sufficient to answer this inquiry by pointing out that the difficulties arising from a closure with heat should be remedied by a closure without heat—there being appliances old in the art suitable for making it.

Treating the patent as broad in scope or narrow in scope, it is, in my opinion, void for want of invention. It must be borne in mind that this is not a case where special consideration must be given to a simple expedient because it accomplishes a result long sought for, but never attained. There is nothing in the record to indicate that any one other than the owner of the Maglinani process sought to remedy its deficiencies, and this patent was applied for soon after the Maglinani patent was granted.

In my opinion, the decree of the Circuit Court should be affirmed, with costs.

BECKWITH V. MALLEABLE IRON RANGE CO.

(Circuit Court, E. D. Wisconsin, January 21, 1910.)

1. PATENTS (§ 165*)—CONSTRUCTION OF CLAIMS—REFERENCE TO SPECIFICATION.

While the courts lean toward reading into the claims of a patent such limitations as will save the real invention as disclosed by the specification and the prior art, where claims employ broad and nebulous terms for the apparent purpose of enabling the patentee to monopolize an important industry, the claims will not be narrowed beyond the boundaries clearly warranted by the specification.

[Ed. Note.—For other cases, see Patents, Dec. Dig. § 165.*]

2. PATENTS (§ 165*)—CONSTRUCTION OF CLAIMS—"CONVEX" SURFACE.

The word "convex," used in the claims of a patent as applied to a surface, is to be given its generally accepted meaning, as indicating a surface of a more or less spherical form rather than cylindrical.

[Ed. Note.—For other cases, see Patents, Dec. Dig. § 165.*]

3. PATENTS (§ 35*)—EVIDENCE OF INVENTION—COMMERCIAL SUCCESS.

The great commercial success of a patented device may turn the scale on the question of invention in a doubtful case.

[Ed. Note.—For other cases, see Patents, Cent. Dig. § 39; Dec. Dig. § 35.*]

Utility, extent of use and commercial success as evidence of invention, see note to *Dolg v. Morgan Mach. Co.*, 59 C. C. A. 620.]

*For other cases see same topic & § NUMBER in Dec. & Am. Digs. 1907 to date, & Repr. Indexes

FIG. 3 COMPLETE TYPICAL DIGEST OF A LEGAL DECISION

Each guide card of a main class has a number as well as a name, and the numbers, although not consecutive, are in a progressive order. The numbering of these cards progressively fixes the proper position of each one in the digest as a whole. The leaving of unused numbers between the main guide cards is for the purpose of allowing the introduction of new guide cards in their proper intermediate positions as occasion may arise. The main guide cards are numbered successively, and arranged alphabetically, which enables one to find a proper main guide card quickly. The sub-guide cards under each main card are not only arranged alphabetically, but each one is designated by a letter of the alphabet. These successive letters fix the

relative positions of the sub-guide cards in their main class. This arrangement of numbering the main cards and lettering the sub-class cards enables each syllabus card to be correspondingly numbered and lettered so that it can be correctly replaced after it has been used. Further, the syllabus cards in each sub-class are numbered consecutively, so that it can be told whether or not any card is missing, and, if so, what is its number.

It seems clear to me that the general plan of digesting and classifying the separate points or sub-topics in the

bus go only so far as to indicate the name or nature of the point being digested, so as merely to tell the searcher in what papers there is any information upon the point. This would make it necessary for the searcher to consult each paper in which the point was treated, but it would save him the trouble of looking at all other papers on the same general subject which might, by any possibility, treat the point, and it would indicate to him the precise page on which the point appeared in those papers in which the point was treated.

The second way in which the points might be digested is to have the syllabi indicate the nature of the point digested, and how the point is treated in the paper. This form of digesting would not only have all of the advantages of the preceding form, but it would often save the engineer from getting out the volume in which the paper appeared and looking at the paper itself, because it would enable him to judge whether or not it is likely to give the precise information he wished.

As an example of the first form of digesting, in which the nature of the point only is indicated, without disclosing how it is treated, the following might be given:

MACHINE ELEMENTS GEARING

Kind of steel for gears subjected to heavy duty, and details of treatment and machining are given.
Gears for Machine Tool Drives, by John Parker, 1913 Proceedings, p. 785, at p. 787.

As an example of the second form of digesting, in which the nature of the point is stated and also the manner in which the point is treated, the following may be given:

MACHINE ELEMENTS GEARING

For gears of small proportions, but subjected to very heavy duty, a five per cent nickel-steel has been found excellent. Blanks are preferably drop-forged and given an oil treatment by heating to 1550 F., and quenching in oil; then annealed by reheating to 1350 F. and cooling very slowly before machining. After machining, gears are carburized by packing in carbonizing material, and heated to 1700 F. in the absence of air for three or four hours. After cooling in the packing, they are then reheated to 1350 F. and quenched in oil, and again reheated to 1380 F. and quenched.

Gears for Machine Tool Drives, by John Parker, 1913 Proceedings, p. 785, at p. 787.

This second form of digesting, while more expensive, might well give the engineer all he wished to know on the point, or, if not, might show him that the information of the paper on the point is along different lines from those on which he was seeking information.

When the digesting is once up to date, the expense of it would be unimportant and by digesting only the principal or generic points of a paper, and not attempting to digest the subordinate or specific points, the expense could be reduced, and the labor of the searcher upon the specific points would be very greatly reduced, because unless a paper contained the generic point, there would be no possibility of its containing the specific point.

It would, of course, be necessary to make the digest or syllabi cards, and also to provide a classification of them so that a searcher could put his hand readily on all the cards relating to the particular point on which he was working. Upon this classification problem, the experience of the United States Patent Office would be of considerable use. The Patent Office has had over 1,100,000 United States patents to classify, so that the Examiners, in making a search to determine whether or not an invention disclosed in an application for a patent is new, can readily find all the United States patents relating to the same subject. Not only this, but the classifi-

1002 174 FEDERAL REPORTER.

6. PATENTS (§ 607).—SUIT FOR INFRINGEMENT.—LICENSES.—BURDEN OF PROOF.

In a suit for infringement of a patent, the burden rests on a defendant to prove the defenses of anticipation or prior use beyond a reasonable doubt.

[Ed. Note.—For other cases, see Patents, Cent. Dig. § 78; Dec. Dig. § 62.*]

7. PATENTS (§ 347).—ANTICIPATION.—PRIOR PATENTS.

Where it is sought to show the state of the art by prior patents, nothing can be used except what is disclosed on the face of such patents which cannot be reconstructed in the light of the invention in suit and so used as a part of the prior art.

[Ed. Note.—For other cases, see Patents, Dec. Dig. § 34.*]

8. PATENTS (§ 657).—ANTICIPATION.—ACCIDENTAL FEATURES OF PRIOR STRUCTURES.

The accidental occurrence of an element or feature of a patented combination in prior structures, where its character and function as subsequently used were not recognized, does not constitute an anticipation.

[Ed. Note.—For other cases, see Patents, Cent. Dig. § 80; Dec. Dig. § 65.*]

9. PATENTS (§ 1677).—CONSTRUCTION.—ANTICIPATION.

The mere casual reference in the specification of a patent to a given feature will not make it a part of the invention, unless it is relied upon in describing the same.

[Ed. Note.—For other cases, see Patents, Cent. Dig. § 243; Dec. Dig. § 167.*]

10. PATENTS (§ 617).—ANTICIPATION.—EVIDENCE.—ACTION OF PATENT OFFICE.

The fact that two applications for patents were pending in the Patent Office and before the same examiner at the same time, and no interference was declared, is evidence that they were not for the same invention, and that one patent does not anticipate the other.

[Ed. Note.—For other cases, see Patents, Cent. Dig. § 77; Dec. Dig. § 61.*]

11. PATENTS (§ 3287).—VALIDITY AND INFRINGEMENT.—RESERVOIR FOR STOVES.

The Beckwith patent, No. 787,425, for a reservoir for stoves and ranges, claim 11, is not void for indefiniteness, nor for anticipation, but discloses patentable invention; the combination showing being one of great utility and success. Also, *held* infringed.

[Ed. Note.—For other cases, see Patents, Dec. Dig. § 328.*]

In Equity. Suit by Arthur K. Beckwith against the Malleable Iron Range Company. Decree for complainant.

This is a bill in equity charging infringement of letters patent of the United States numbered 787,425, issued to complainant April 18, 1905, the application for which was made on the 11th day of September, 1903. Prayer for an injunction and accounting.

The answer denies that complainant was the first inventor and discoverer of the improvements described and claimed in complainant's patent; alleges that the said alleged invention in all material points thereof had been anticipated by a large number of patents, references to which are set out. The answer also sets up prior use of the supposed invention in this country for more than two years prior to the complainant's application, and a list of such prior users is set out. For further answer the defendant alleges that said patent discloses no patentable invention; that its several claims are inexact, incomplete, illegal, and void.

The only claim of complainant's patent involved in this litigation is claim No. 11, which reads as follows:

"1. To a stove or range the combination of the convex and rigid back-plate; the sheet metal reservoir; and means for clamping said reservoir against the convex surface of said plate for the purpose specified."

FIG 3A COMPLETE TYPICAL DIGEST OF A LEGAL DECISION

decisions of the Courts, can be applied with great advantage to the publications of the Society, although it would require some modification and adaptation in carrying out the details. The most desirable procedure would apparently be to begin by digesting all papers which are published by the Society from now on, and, in between times, to work backward through the publications until ultimately the Transactions and the Journals would be fully digested.

There are two ways in which the digesting could be done according to the amount of time and expense it was desired to spend upon it. The first way would be to have the syllabi

cation has been carried out to great sub-division so that when the Examiner is searching for particular details of an invention he may find all the patents which might have such details, separated out into a comparatively small sub-class, and thus reduce his labor to the smallest proportions.

The sub-division of class No. 164 of Cutting and Punching Sheets and Bars, is here reproduced as a typical example of the manner in which the Patent Office classifies all of the patents relating to one particular art (Fig. 4).

CLASS 164.—CUTTING AND PUNCHING SHEETS AND BARS. (XIV.)

(See Definitions of Revised Classes.)

Subclasses.

Buttonholes—		Cutting—	
1. Knives.		Machines—	
2. Machines.		Rotary cutter—	
3. Pliers.	69.	Rotary work-mandrel.	
4. Modified scissors.	65.	Slitters and winders.	
5. Scissors attachments.	66.	Transverse—	
11. Combined machines—	68.	Work-feeding—	
13. Die cutting and punching.	67.	Printing press attachment—	
14. Pivoted knife-carrier.	61.	Work-feeding—	
15. Reciprocating knife-carrier.	62.	Reciprocating feed—	
16. Roller-cutter and punch.	71.	Sweep-cutter—	
17. Work-feeding.	72.	Elliptical work.	
18. Die—	73.	Traveling cutter-carriage—	
29. Dies—	74.	Motor-driven cutter—	
31. Adjustable-face.	75.	Reciprocating.	
33. Blank-ejecting.	76.	Rotary.	
32. Multiple concentric.	77.	Roller-knife.	
30. Spiral-strip-cutting.		Expanded metal—	
19. Machines—	65.	Reciprocating.	
23. Reciprocating cross-head—	66.	Roller.	
24. Shifting dies.	7.	Fence-barbs—	
25. Reciprocating planer.	8.	Cutters and dies—	
26. Lever-operated.	9.	Roller.	
27. Screw-operated.	10.	Processes.	
28. Roller-die.	10.5.	Printer's leads.	
29. Work-feeding.	85.	Punching—	
21. Reciprocating feeder.	119.	Implement—	
22. Roller-feed.	120.	Pivoted handles—	
80. Implements—	121.	Pliers.	
81. Pliers.	122.	Turned.	
82. Sweep.	123.	Traveling-roller.	
83. Traveling—	86.	Machines—	
84. Roller-cutter.	118.	Dies and die-holders.	
34. Machines—	87.	Feeding and punch—	
78. Band-knife.	88.	lug—	
79. Cutting-tables—	89.	Reciprocating-feed.	
36. Fixed-cutter.	116.	Roller-feed.	
37. Spiral-strip.	117.	Feed mechanisms—	
38. Work-feeding—	117.	Reciprocating.	
39. Roller-feed.	91.	Lever-operated—	
40. Oscillating apertured cutters.	92.	Foot.	
41. Pivoted-cutter—	93.	Pattern.	
44. Lever-operated—	94.	Hammer.	
46. Compound leverage.	95.	Hydraulic.	
45. Work-clamping.	96.	Lever-operated—	
43. Transverse.	97.	Foot.	
42. Work-feeding.	98.	Printer's rules.	
47. Reciprocating-cutter—	111.	Punch-selector—	
51. Automatic-clamp.	112.	Keyboard-controlled.	
48. Cutters and bed blocks.	113.	Electrically-operated.	
53. Draw-cut.	114.	Pattern-controlled—	
54. Automatic-clamp.	115.	Electrically-operated.	
55. Separately-operated clamp.	116.	Roller—	
56. Fluid-operated.	100.	Printing-press attachment—	
57. Gages.	101.	Screw-operated.	
59. Lever-operated.	102.	Shaft-driven—	
50. Notches work.	107.	Safety devices.	
52. Separately-operated clamp.	104.	Stop devices.	
48. Work-feeding—	105.	Shaft-clutch.	
49. Roller-feed.	106.	Stroke adjustments.	
60. Rotary cutter.	103.	Tilting-frame.	
63. Curved platework.	110.	Strippers and hold-downs.	
70. Cutters.	109.	Tie-band tongue.	
64. Notched work.	108.	Tube.	
	125.	Processes.	
	124.	Punches.	
	106.	Scrap-cutting.	

FIG. 4. TYPICAL PATENT OFFICE CLASSIFICATION OF AN ART

While the Patent Office has carried the sub-division of its classification greatly beyond what would be necessary for this Society, still its work would be very useful in devising a classification for a digest for the Society. The Society would only be interested in a relatively small proportion of the entire two hundred and fifty main classes, but the Patent Office arrangement of main classes (together with the definitions of the classes and sub-classes which it

publishes of which Fig. 5 is a portion relating to the class shown in Fig. 4) would serve to sub-divide completely, on broad lines, the entire field of work covered by the Society, without overlapping of the classes.

The larger sub-divisions of the main classes would probably be useful in the Society's classification, although the more minute sub-divisions would probably not be needed.

CLASS 164.—CUTTING AND PUNCHING SHEETS AND BARS.

DEFINITIONS.

Class.

This class embraces machines and processes for cutting, including die cutting and punching sheets, plates, or bars of metal, cloth, rubber, leather, paper, etc.

Machines for splitting and skiving of leather are classified in 63. LEATHER-WORKING. Machines specially designed for working on boots and shoes, except die-cutting, are in class 12. BOOT AND SHOE MAKING.

Subclasses.

1. BUTTONHOLES. Devices for cutting buttonholes, usually in cloth or leather.
2. BUTTONHOLES, MACHINES. Machines for cutting buttonholes.
3. BUTTONHOLES, KNIVES. Buttonhole cutters having a knife form of cutter.
4. BUTTONHOLES, PLIERS. Buttonhole cutters having a plier form.

Search Classes.

164.—CUTTING AND PUNCHING SHEETS AND BARS, subclasses 81. Cutting, implements, Pliers, and 121. Punching, implements, Pivoted handles, Pliers.

81.—Tools, subclass 187. Pipe and rod cutters, Pivoted, and subclasses thereunder.

5. BUTTONHOLES, PLIERS, MODIFIED SCISSORS. Buttonhole cutters in which an ordinary pair of scissors is modified to cut the buttonholes.

6. BUTTONHOLES, PLIERS, SCISSORS ATTACHMENTS. Devices adapted to be secured to ordinary scissors to cut the buttonholes.

6.5. EXPANDED METAL. RECIPROCATING. Machines provided with a reciprocating cutter adapted to slit sheet metal and also provided with means for corrugating or for stretching the sheet.

Note.—Machines for forming expanded metallic lath are classified in this subclass. Machines for forming corrugated metallic lath are classified in class 153. METAL-BENDING.

FIG. 5. DEFINITIONS OF CLASSES IN FIG. 4

It would not be necessary that the Society's digest be printed or published, but if a single, hand-written digest were maintained in the Society's rooms, it could be used by every member of the Society either by personal access to it, or by ordering complete copies of all the digest cards on a particular topic or, at least, a list of the volume and page-numbers of such cards.

The work of digesting the current papers might be considerably reduced by asking those members who were willing to do so, to digest their own papers, although it would probably be desirable to have such digests revised by the person whose duty it was to do the digesting in general.

I believe that a single competent man, working under the supervision of a Committee, could digest the current papers and have the bulk of his time for working backward, digesting the Transactions and Journals, so that in the course of two or three years the entire literature of the Society would be digested. Such a man, to be most successful, would need to be not only able to understand the papers he was digesting, but to be capable of generalization, so that he could condense a section of a paper while preserving its true proportion and import.

In the light of many years' experience with the proposed plan of digesting and classifying records, as it has been applied to the records of the profession of the law, I feel confident that it is thoroughly feasible and practicable to apply it to the records of the profession of mechanical engineering, and long experience with the classification of the

Patent Office leads me to believe it would be of much aid in adapting the system to engineering records. The expense to the Society would not need to be burdensome, as one man could accomplish the work within a reasonable time, and such expense would be small compared with the value of the time saved to the members of the Society. The effect upon the publications of the Society would be to make each paper perpetually "current" instead of their now being usually ephemeral. I recommend, therefore, that the Council be asked to appoint a Committee to consider the question.

DISCUSSION

SELEY HAAR expressed the opinion that a digest of the records of the Society would be of less value to engineers than to lawyers. For although it would eliminate most of the labor of acquiring knowledge, it would tend to make one unlikely to remember what he wanted, when he wanted to use this material again. Besides that, the engineer would usually need to get the information much quicker than is necessary in law and patent cases, and would not have time to refer to a digest, which would be too bulky for ready reference.

A. M. COYLE said that he considered the author's idea one of the best suggestions that had been offered to the Society. Much time is wasted in hunting for information, and there is a vast amount of useful material published by the Society, which becomes useless because it is too difficult to find. He suggested that instead of a manuscript digest kept in the Library, there should be a system of cards to be issued to members, at an expense not to exceed \$1.00 a year. The slight amount each would pay would very nearly cover the cost of the digest. Once started, the plan would be self-sustaining not only for members, but for a great many other people who would be glad to have the information.

WILLIAM KENT expressed his appreciation of the paper, and said that the need for such a digest as Mr. Prindle proposed was an increasing one. He suggested that there would be a great deal of cross-indexing for each paper. For example, the paper by D. S. Jacobus, Tests at the Detroit Edison Company's Plant, might be placed under the general head of steam boilers, but should also be cross-referenced under the head of labor questions, because there is in it a statement how to pay wages in the boiler room.

THEODORE STEBBINS suggested that the Society bear a part of the expense, and a notice be put in *The Journal* to find out how many would subscribe for these cards, so that the expense might be borne partly by the Society. He thought that besides the set of cards in the Society rooms, there should also be a set on file in the Library and that manufacturers and others who wanted cards should subscribe and finance the scheme in that way. He believed that the records for the current and the future years should be rather fully compiled, and that for previous years, a shorter method be followed to save expense and expedite the work.

HENRY HESS contributed a written discussion, in which he said that while the indexing and digesting of the material in the Transactions would be useful, the scope would be

limited, just as the digest of only one court would be of limited use. An engineering digest to be broadly useful should include the work of the four National Engineering Societies, and probably also the matter contained in the foremost engineering publications. Moreover, the engineer who would fully post himself on any given subject would have to search not only the literature of the United States, but that of the principal foreign countries as well.

The necessity of something of this nature has long been recognized. Partial digests have been published in the United States, in England, in Germany, in France and in Belgium. Probably the most ambitious undertaking of its kind, the *Technische Auskunft*, until recently issued every month, was a volume covering the entire world's technical literature in five languages. In Belgium, a monthly *Revue Technique* is published and indexed under the Dewey system. It is thus clear that there exists a very general demand for this work, but it is equally clear that the demand can best be supplied under the auspices of an association that is not primarily intended for profit making. There is little doubt the work could be made self-supporting, in time, once it is thoroughly started and carried to a point where its value can be recognized. Mr. Hess suggested that the Council refer the matter to the Engineering Foundation, through which the scope would at once be extended to cover the four national societies, associated in the Foundation.

A. M. COYLE said that what Mr. Hess suggested would cover such an enormous area, that it would be difficult to reap any results in the near future. Without delaying in any way the general ideas of Mr. Hess, the American Society of Mechanical Engineers could proceed with its own records as a start.

WILLIAM KENT said that he would like to see this undertaken by the Society first, and after it had been systematized, the other societies might get out similar cards. He suggested that a conference committee of representatives of the different societies should get up a scheme of indexing that would meet the needs of all the societies.

SELEY HAAR pointed out the fact that this digesting was not entirely new in the four societies. The American Institute of Electrical Engineers has for some time been presenting with each paper a digest of what it contains. The very complete index of all the Transactions of the Institute, published about a year ago, is so thoroughly cross-referenced that it would serve as a digest. In any intersociety undertaking it would be necessary to reckon with the work already done.

THE AUTHOR said in closing that he believed it would be better to start the plan within the society, and to leave to the Council the matter of passing it on to the Engineering Foundation. Otherwise the idea would be so expanded, that it would be likely to fall from its own weight. In answering Professor Kent's remarks on cross referencing, he said that his idea was not to put on a single card the entire digest of a paper, but only the point or points which would go under one sub-division of the classification. It would be possible to assemble on one card perhaps three or four points from different papers, but only such as would go under one sub-division. In this way cross-referencing is avoided in legal, and could be avoided in engineering digests.

BOSTON SYMPOSIUM ON EMPLOYMENT AND EDUCATION

A Joint Meeting of The American Society of Mechanical Engineers, the American Institute of Electrical Engineers and the Boston Society of Civil Engineers was held at Wentworth Institute on the evening of February 26th. A buffet supper was served, after which the new shops and laboratories of the students were inspected. There were over 200 present, and at eight o'clock the audience assembled to listen to a series of addresses, an account of which is given below.

At a joint meeting in Boston held on the evening of February 26th at Wentworth Institute, four addresses were given on subjects relating to employment and education. These were: The Responsibility of the Manufacturer for Training of Foremen and Skilled Workmen by Mr. Walter C. Fish, manager Lynn Works, General Electric Company; The Employer's Side of the Problems of Irregular Employment by Mr. Henry S. Dennison, treasurer, Dennison Manufacturing Company; Coöperation between Employers and the Schools by Mr. William B. Hunter, director of Fitchburg Industrial Schools; and The Economic Relation between the Supply of Skilled and Intelligent Workmen and Unemployment of the Masses by Prof. Thomas N. Carver, of Harvard University.

The meeting was opened by Principal Arthur L. Williston of Wentworth Institute who said in welcoming the guests that the endeavor of the Institute had not been to reach up into the higher fields of technical education. It was a trade school for the training of the workmen, foremen and master mechanics of industrial plants; and although those who were present were engineers he felt that they and the Institute had a vast field in common.

ADDRESS BY WALTER C. FISH

Mr. Fish said that he wanted to enlarge his subject at least temporarily so that it would become "The Responsibility of the Community for the Training of Foremen and Skilled Workmen." The manufacturer is helpless if he does not get the coöperation of the community which has such vital interests in the matter and if the manufacturer does not get a decent product from the community his task is correspondingly accentuated. The manufacturer is largely dependent on the educators of the community and the future of this country depends ultimately on education and average intelligence. Mr. Fish also expressed the belief that the early school training of the young man destined to become an artisan should be as far as possible along lines leading to a good general education, and the workshops of the country should take more active interest and more responsibility in supplementing this education. To emphasize this conviction the speaker read an extract from Huxley's essay on Technical Education written in 1877. While some might say that men of that time were likely to be behind the times from the standpoint of today he thought it was fair to say that Mr. Huxley was many, many years ahead of his time. Mr. Huxley said:

The workshop is the only real school for a handicraft. The education which precedes that of the workshop should be entirely devoted to the strengthening of the body, the elevation of the moral faculties, and the cultivation of the intelligence; and especially to the imbuing the mind with a broad and clear view of the laws of that natural world with the components of which the handicraftsman will have to deal. And the earlier the period of life at which the

handicraftsman has to enter into actual practice of his craft, the more important is it that he should devote the precious hours of preliminary education to things of the mind which have no direct and immediate bearing on this branch of industry though they lie at the foundation of all realities.

The speaker, continuing, said that for the last few years he had had more or less control over a large body of men and had constantly been in contact with their work. The practical results of his observation were precisely those suggested by the words of Mr. Huxley. Regardless of whether the young man comes from the grammar school, the high school or a school like Wentworth Institute, his education must be finished in the workshop if he is to be a successful artisan. The manufacturers must round off his education because it is only in the shop that he can obtain certain things which he must have if he is to be successful. Manufacturers must become educators and must more and more attempt the performance of those things which perhaps would have subjected them to ridicule if they had been attempted fifteen or twenty years ago. He would prefer to have a young man come to him who really understood the actual causes of the American Revolution or the Rebellion or the French Revolution than one who perhaps had been taught elementary molding or carpentry. The former was likely to be broader and better and more successful.

This is not an attack on vocational schools; the main thing is to keep the young man at school and certainly in this respect the vocational schools of this country are serving a most useful purpose. They attract and educate many who would leave the public schools at too early an age but who will not leave vocational schools.

Young people leave the public schools at fourteen or fifteen years of age because the public schools of today are not interesting. Many teachers who are thoroughly conscientious and hard-working have not been taught to make grammar and the other so-called dull studies interesting. These things are up to the community and not up to the manufacturer who is not obtaining any too good a product for his workshop. It must be remembered that the manufacturer has to deal with people of whom a large percentage are common people, suited, when they enter his establishment, to do common things. It seems fair to say that not more than one or two at the most out of every ten who enter industrial establishments have any reason to be considered subjects for marked advancement or for educational work on the part of the manufacturer. What shall be done with these one or two out of ten, or it is better still to say five or six out of a hundred? The best answer at the present time appears to be to organize freely and maintain apprenticeship systems. If a young man is to be started in a career he must be guided, by which is meant that he must learn practical things by system. We should make apprenticeships more flexible so that our workshop students will not all be treated in the same way. Better recognition

must be had of the experience and education of each individual to the end that when the boy reaches certain set results, he will pass out of the apprenticeship system into his life work.

The fact was emphasized that the foremen are found, not made. The principal qualification of a foreman is in his own proper individuality which depends in large part on extremely early influences and perhaps more or less upon heredity. The first thing any successful foreman has to learn is the ability to put himself in the other fellow's position. He must not only be a man of good disposition, but one of breadth and understanding.

No one can take ten graduates from any school and teach them to be men of good disposition, possessing the innate characteristics essential for good leadership. If they are not born with these faculties the only thing will be to find others who are.

What is a foreman? In different corners of the shop he must possess all sorts of different qualifications. He may be put into a department where he controls 80 per cent material and 20 per cent labor; he may be placed in a department where he controls 80 per cent labor and 20 per cent material. In this latter department there may be no machinery at all, while in the former department he may have charge of the most complicated machinery. A great deal is said nowadays about efficiency of organization and the importance of the question cannot be overstated. Most manufacturers, unfortunately, find they still must organize with reference to available material, and the qualifications of disposition and ability to control men are often missing in those candidates for foremanship who possess marked abilities in other directions.—technical and mechanical, for instance. There are no definite specifications, and the successful manufacturer will seek in each case for the man who, though helped and trained by his school and apprenticeship life, will have largely made himself suited for the position.

ADDRESS BY WILLIAM B. HUNTER

In considering the subject of Coöperation between Employers and the Schools, William B. Hunter said that we hear a great deal of criticism by employers of the product that the schools are turning into their shops, while the boys on their part do not know what trade or business they are fitted for on leaving the grammar or high school.

This is one of the phases of the situation particularly recognized by the cooperative system carried on at Fitchburg, Mass. It was organized because a business man saw that it was a business way of furnishing boys to business houses.

After the boy has spent one year in the high school, he goes to work in a shop as an apprentice. He spends one week in the shop and the next week in the school. He is registered in the shop one whole week and the next week when he goes back to school his place is taken in the shop by another boy. In that way there is no idle machinery and no idle school; machines always going—schools always going.

It is real business for the boy in the shop, unlike most school shops where everything is ideal. The manufacturer takes an intelligent interest in the boy and if the boy is not going right, he sees it. He does not have to take it for granted that the school is teaching this or that; he sees results. The boy is in the shop to work and he is paid by the hour. It is a commercial proposition, not philanthropic.

It is firmly believed that the public schools should take care of this plan of education. The employer is already taxed for public education and the public schools are responsible for the training of our young people. Public school training is the best for the boy. Why should the employer have to duplicate the public school system by putting in a school in his own plant? Instead of erecting another school building the capacity of the present school building is doubled by this system since only one-half of the boys are in school at one time. Then as to the manufacturer who is going to take care of the boys afterward, why should he not be willing to help make better workmen of them? It is a better plan for the manufacturer, and it is better for the boy.

How about loyalty? When a boy starts an apprenticeship course and grows up he certainly will be loyal. If he serves his time with Brown & Sharpe, for instance, later when he goes out he will talk for Brown & Sharpe and the things he saw there. We have found this to be true.

The idea of giving wages to the boys makes it possible for them to continue in the high school; otherwise he might have to drop out before finishing his course. He cannot afford to go to the trade school. The rate paid to the boys the first year is 10 cents an hour—not much but it helps considerably. In a good many cases this is the means of keeping the boy at school. He gets a little more the second year and a little more still the third year.

The average boy after leaving high school is trying his hand at this and at that. He does not know what he is fitted for. With us, if the boy sticks to his course to the finish he has a definite trade with which he can go out and earn his living, not alone in the shop where he spent alternate weeks while at school, but in any other shop.

It has been asked why boys leave the high school. When a boy gets to be about fourteen he wants to earn something and not be obliged to have to ask his father for a quarter now and then. Our cooperative system satisfies the boy's desire to earn money, which makes him willing to remain at school. This is better than having the boy drop his school work and go out to take the first job he can get regardless of what it is, so long as it offers wages.

Then, after graduation he is assured of a job. He is actually a journeyman when he gets through and can go into another city and earn \$3.00 a day. He not only has his shop experience, but while in school has been studying shop problems. He has become acquainted with the problems of the workmen and is more serious and earnest than the high school boys who often remain in school simply as an excuse for having a good time. He has learned that a working man is just as good as anybody else, that work is honorable, and that one who gets his hands dirty by work is just as good as one who does not. This is not always the attitude of the young men coming from our high schools. Thus we are teaching the boys democracy and they do not fear that they will be looked down upon for going to work in the shops after graduation.

A good many of the manufacturers visit the schools and help solve some of its problems. We teach in Fitchburg the metal trades and allied trades: machine-work, pattern-making, saw-making, drafting, iron-molding, tin-fitting, piping, printing, textile and office work, and it is planned later to take up the building trades and even farming. The manufacturer meets with the director each month and discusses the

various problems as they come up. He tells what we ought to do to help him and we frequently go around to the shop and see for ourselves.

A number of leading firms in Fitchburg are coöperating with this school. Most of the larger machine shops and textile plants have been willing to take some of our boys every year which shows the plan to be a success. This idea is not confined to Fitchburg alone. There are similar undertakings at Providence, R. I., Springfield, Vt., Chicago, Ill., York, Pa., Lansing, Mich. and other places. It does not cost anything to start the system; no shops or machinery have to be put in the school, but instead, the live commercial going shops of the city may be used. Our cities are all poor. By our coöperative method, they are getting dividends on education. Our boys have made over \$100,000.00 which has gone into the pockets of the citizens. It is giving the workman an education so that he will make a better workman and be fitted in many cases for a future foreman.

ADDRESS BY PROF. THOMAS N. CARVER

Professor Carver spoke on The Economic Relation Between the Supply of Skilled and Intelligent Workmen and Unemployment of the Masses. He said that one of the elementary commonplaces of economics is the observation that all men do in industry is to move things about from one place to another. Back of this process of moving things there is at least a purpose, which, it may be fairly stated, is to get things together in the right proportion.

Whether one is a chemist mixing a compound in a laboratory or an engineer digging a swamp, irrigating a dry plain, or erecting a building, he is simply trying to get things together in the right proportion. All this requires human labor, and today the distribution of human talent has more to do with the bad distribution of wealth than any other single factor. In comparison with this, other things are trivial—getting human talents of various kinds combined in the right proportion.

Now suppose that material things are in the wrong proportion for common use, as, for example, the water in the swamp just referred to, there being too much water in proportion to the soil. While it may be perfectly good water, it is not worth much there. Only a certain supply of water is necessary to make plants grow. It is the bad proportion between water and soil which makes water so cheap.

Again, if one is trying to make gunpowder which is composed of a mixture of saltpeter, sulphur and charcoal, he may have more charcoal than he can use but not a sufficient supply of one of the necessary materials. Charcoal must therefore be cheap. This illustrates just the problem that is met with in unemployment. One can try a laboratory experiment and put the proposition to the acid test. Let one disguise himself as an unskilled workman and go out looking for an employer. Then go out as an employer looking for unskilled workmen and see under which condition there is the greater difficulty. The situation is exactly the same as in the case of gunpowder in our illustration—no matter how great the demand for gunpowder one cannot use the charcoal. The charcoal is out of employment because one cannot find enough saltpeter to mix with it.

It would seem as though since there is a demand for commodities, there should also be a demand for labor. The demand for commodities in itself will not and does not give

employment unless there is something else. No matter how great the demand for commodities nor how great the supply of manual labor, unless there is the employing talent in between, you cannot use that human labor. This is a bad distribution of human talent; too much of one kind and not enough of another kind.

There is an idea abroad that there must be available means of employment for everybody. Since labor produces all the wealth, there must be a demand for labor. But here is where the first principle of economics should be applied. There must be some other things besides unskilled labor, if wealth is desired. The difficulty is that there is not a sufficient supply of skilled labor to do the skilled part while the others do the unskilled part; splendid charcoal but not enough saltpeter.

Now if it were possible by some miracle to transform the charcoal into saltpeter it would, of course, be an immense help to the situation. By transforming a little of the charcoal into saltpeter one could then use the balance of charcoal. Similarly, if we could only transform one kind of labor into another, our problem would be solved. The chief value of education of any kind is that it tends to redistribute human talent and train men for positions where men are scarce. That is the miracle which will transform the charcoal into saltpeter. Put these things together in the right proportion and if we can do this thoroughly there will no longer be unemployment.

This trade training is excellent as far as it goes, but there is danger that it may stop too soon. Our greatest need is not for skilled laborers. Of course we need them, but employers are what we want. What we ought to do is to try to bring about conditions where there will be two employers where there now is one. Make more employment for labor and wages will rise.

There are different kinds of skilled labor which have to be combined: the skilled labor of the manager and of the investor, the man who knows how to start an enterprise. The man most needed is the man who can see opportunity for a new enterprise, and not only see it but make it go and produce a favorable balance sheet,—such a man is even more important than he who can make two blades of grass grow where only one grew before.

There is no such thing as eliminating poverty or unemployment until we make employment enough to absorb all the men who are now looking for jobs, and a little more,—until we can make two jobs where there is but one man, so that the employer has a hard time finding labor. Employment must be more plentiful than labor. At the present time perhaps ten men will apply for one job. Poverty will be eliminated when conditions are reversed and ten employers will be seeking the services of the same man.

It just depends upon how much we really want to get rid of unemployment and of poverty. If we want to enough we can do it. It will mean a harder time securing workers if we have to compete for every man. Chasing after him will mean a little more inconvenience, but wages will be better for the workmen.

In addition to increasing the number of employers, we can do something toward thinning out the number of the unskilled. Education is itself thinning out these numbers. Every time a man is trained out of the unskilled class there is one man less there, unless more come in from the out-

side, and a little restriction at that point would be beneficial. Some restriction of the inflow of labor from the outside would go a long way toward thinning out the ranks of the unskilled. After a while when the employer advertised for a workman, there would not be anybody after the job.

This point is so absolutely clear and simple that I do not take anybody seriously who professes to have any interest in the labor problem and yet does not want to see immigration restricted. It sounds well to say that we must keep our doors open to the poor and oppressed of the world, but I am inclined to think that the appeal to the pocketbook is rather stronger than the appeal to sympathy.

About equality: If one man can do twice as much as another, he is worth twice as much. As between bricklayers and bank presidents there can be equality by making it as hard to find a bricklayer as it is to find a bank president and their wages will be the same. All this comes down to the question of supply and demand.

To go back to the saltpeter argument. In the condition where there is more charcoal than will combine with the smaller supply of saltpeter existing, one will be cheap and the other will be dear. There is nothing unjust about it. The price of one depends upon the existing supply of the other when they both have to be combined to make the gunpowder. The only way to equalize the value is to produce more of the saltpeter or shorten the supply of charcoal. It is a very plain question of supply and demand.

On the dry plain, water is necessary for the production of plant life. Water should be worth a good deal there, but it is not worth so much in the swamp where there is too much of it. If we could bring the water from the swamp to the dry plain, the ideal condition would be reached. In the same way labor is more productive and profitable where there is opportunity to use it. When one kind of labor is as much needed as another there will be equality.

ADDRESS BY HENRY S. DENNISON

In speaking of Irregular Employment, Mr. Dennison said in part, there are three classes into which we must divide irregular employment in order to see it at all clearly. One has to do with the long cyclic changes of business prosperity and depression; another with business changes due to the season of the year; and the third, with the rate of labor turnover in mills and factories,—that is, the frequency of hiring and firing.

Let us consider some of the waste which is caused by irregular employment. Mr. M. W. Alexander of the General Electric Company has worked out figures showing estimates ranging from \$39 to \$150 as the cost of each new employee, and when one considers the amount of spoiled work, the amount lost on overhead from short product, the cost of training the new man, the cost of hiring, etc., \$30 is a pretty conservative estimate of the loss caused by hiring a new employee.

Another loss which comes from irregular employment is due to the slackening of speed during the dull seasons and the difficulty of getting back speed when times become better. Even where the employees are on piece rate, they will take all the time they like in such off seasons because there is only a limited amount of work for them and after such periods, it takes a long time for many people to get back into the stride again. Then there is the opposite extreme

of overtime at the opposite stage of the season. The factory that can run with a given crew, that gets more and more into its stride and more and more productive, is a lucky shop.

In the building trades where the men are able to find employment only at certain times during the year, they must have high rates of wages for the time they do work to make up for the periods when they are without work. In many cases a long period of unemployment causes permanent injury to the efficiency of the workman.

Again, in connection with shifting employment is the lack of loyalty. Loyalty cannot be developed in the employee who is jumping about from shop to shop.

So much for the cost of irregular employment. What can we say as to the causes and possible chances for improvement? In connection with the cycles of business depression and prosperity, one cause of our difficulty is our complete lack of information about real business conditions at any given date. Many things ought to be known about the stock on hand, about the actual volume of trade, etc. If we could see more clearly where we were at any stage of the game, we could provide more wisely and provision against future difficulties would do more than anything else to prevent those difficulties from coming. If we have gone along in a period of prosperity and signs indicate that sooner or later we shall have a period of depression and we hedge a little for it, the general results will be more wholesome; for while we shall not have so much prosperity for the time being in consequence, neither shall we have so much depression at a later period.

For the seasonal unemployment the causes all finally rest upon weather conditions which affect building trades, the handling of perishable food-stuffs, and indirectly the styles of clothing. One influence that may work toward the betterment of seasonal irregularities is the closer relation between the manufacturing and the selling ends. This we have found, ourselves, to be extremely valuable. Letting both of these departments run without intimate connection caused very considerable difficulties, whereas, when we brought them together and made each serve the other we found large improvements in getting orders out earlier for delivery, anticipation of orders wherever possible, etc.

The weather conditions which affect the building trades to such a large extent presents a technical problem extraordinarily difficult. During some months the contractors do not keep more than 5 per cent of their men and the other 95 per cent are discharged. And even though some of these men—bricklayers, carpenters, etc.—do receive \$5.00 per day while they work, this often means only \$600 or \$700 a year as their total income. Every effort possible must be made to regularize these trades.

The effect of weather conditions in other trades, such as in the candy trade, for instance, has been considerably helped by the refrigerating process; and other technical means can be found to avoid these other difficulties if we are only persistent enough about it.

The irregularity of employment which results from a rapid labor turn-over is a very serious loss to employers, which is very little appreciated. Mr. Alexander found in a group of factories which employed 38,700 employees at the beginning of the year 1912, and 46,800 at the end of the year, that they had hired 44,365 people, indicating that over 36,000 people had dropped out of employment during the

year. Allowing for all the inevitable causes of withdrawal, such as death, sickness, etc., he finds in these industries over 22,000 people engaged above the seemingly necessary requirements. This means to these industries a loss of at least \$750,000 a year. In one employing 11,000 people at the beginning of the year, he found that 17,000 had been hired through the year with practically no permanent increase in the crew. And in all the labor turn-over exceeds 50 per cent.

The causes are many and vary somewhat with each factory. They can probably be studied best and most readily corrected through the establishment of a very efficient employment department.

In all these three classes of irregular employment the employer has the largest opportunity to improve conditions and has also the largest amount at stake. Here is a preventable waste, costly to employer and employee alike, in which any improvement will be of financial benefit, will be a help to our country in competition with other nations, and will be a social service.

WENTWORTH INSTITUTE

Wentworth Institute, which acted as host of the evening, was opened three and a half years ago, founded by Aricoh Wentworth, a marble manufacturer of Boston, who bequeathed in his will \$3,500,000 for the purpose.

The institute aims to train workmen of the most competent and expert type, foremen and master mechanics. The shops and laboratories, which were inspected at the time of the meeting, are admirably adapted to the special purposes of instruction for which they are planned and their equipment is most complete.

During the short time that the school has been in existence it has grown rapidly and now has nearly 1300 pupils enrolled in its day and evening classes and additional buildings are soon to be erected. It has already given instruction to 3820 students and granted certificates of graduation to over 875 persons who have completed its courses.

The instruction which is offered is of two grades: first, short one-year courses for young men who wish with experience to become high grade mechanics; and second, longer courses for those who have already had practical experience and who wish to become foremen, master mechanics, or superintendents. A wide variety of courses is offered and the aim is to reproduce actual commercial conditions in the shops and laboratories of the school and to work out new courses of applied science as required for the various trades or branches of industry to supplement and go parallel with the practical instruction. This enables the student to understand the technical features of his trade and the fundamental principles of science upon which the trade is based.

SUBMARINES

BY G. E. FURBUSH, SYRACUSE, N. Y.

Student-Member

At a meeting of the Syracuse University Student Branch of the Society held February 12, 1915, an interesting illustrated address was presented on the subject of the modern submarine boat, by Grant E. Furbush, secretary of the Syracuse Student Branch, which proved of interest in view of the active part that has been taken by this form of water craft in the present European war. The author traced the history of submarine boats from the crude efforts of Symons in 1747 up to the present time, and gave detailed information concerning modern practices in this country and abroad. His conclusions, drawn from a careful study of present developments, are of interest, and are here given.

From the mechanical point of view, the submarine is still in a transitory state. Until it is made more powerful, given a higher speed, and has a much wider radius of action, its success must be limited, even in attacking vessels in harbors, particularly in the presence of the latest system of submarine defense. All of these qualities call for increased dimensions, which increase their cost and reduce their handiness, especially in harbors and comparatively shallow waters.

Every increase in the size of a submarine also adds to its visibility when running awash, and increases the time and distance required for disappearing if the vessel has to dive.

The difficulty in diving at a steep angle has reference to the electric storage batteries and to other vessels containing liquids where alterations in the level introduce disturbing influences. The acuteness of the angle of dive, also intensifies the difficulty of subsequently bringing the vessel to an even keel, and increases the danger of the vessel striking the bottom, a danger which has involved the loss of at least two submarine boats of comparatively small size. Greater depth of water is required for such operations, so that only small vessels can be used in attacking ships in harbors.

Because of the many variants and the demand for such careful research, slow progress is being made, but the evolution of design can not be hastened. What is demanded on the part of naval authorities is to move with as much rapidity toward improvement as is consistent with the insurance of reliability in each vessel built, and at the same time to maintain as much secrecy as possible.

Thus, from all that has been done the past few months, it is found that the menace of the submarine is really serious. The trouble with it is that it is altogether too small and too slow for deep sea cruising and for the fighting of deep sea battles. When it has reached a displacement of 3,000 tons and can steam at destroyer speed, the type will realize its unquestionable latent destructive power. Then the battleship will have to look to its laurels.

FOREIGN REVIEW AND REVIEW OF THE PROCEEDINGS OF ENGINEERING SOCIETIES

ENGINEERING SURVEY

Every day shows more and more that in engineering nothing should be taken for granted. When first internal combustion engines were designed, the speed of water flowing through the engine jacket was determined off-hand, simply by making the pump as small as could be without alterations, just because the engine ran after a fashion with an efficiency satisfactory for practical purposes. In a paper before the Cleveland Engineering Society, J. B. Merriam shows that the temperature of the water in the jacket has been limited because of secondary phenomena (the formation of bubbles of steam on the walls of the jacket and consequent spheroidal action due to the limited speed of the water). Experiments and then design of machinery of commercial sizes have shown that if the speed of water through the jacket be made approximately ten times as high as usual, the temperature of the water in the jacket can be raised from around 150 deg. to about 250 deg. Fahr. without injurious effects, and thus an interesting way of recovery of heat losses can be devised.

In the Foreign Review Section, the first article is an abstract of an investigation on the action of an air jet on the surrounding air, where the methods of tests are described and velocity, volume and energy curves given. The data obtained in this investigation are of considerable interest for air jet machinery and, to a certain extent, to fan manufacturers.

In the next article is discussed a method of electrically determining the efficiency of large water turbines, describing both the mechanical and the electrical ends of the apparatus and methods used. Both cases of separate and self-excitation are covered and the limit of errors discussed.

Henry Lossier investigates the subject of lateral flexure of hollow pieces and develops new rules for the calculation of stresses in structures consisting of two parallel members united at regular intervals by cross-pieces. He gives a formula which he compares with the old Euler formula and the more modern Timoshenko formula, and shows that his formula agrees fairly closely with the latter.

Prof. J. Fischer Hinnen discusses the question of axial loads on radially loaded ball bearings and shows how a play in the bearing brings about very serious additional pressures on the bearing. He also calls attention to the pitting to which shafts on which ball bearings are running are often subject, and ascribes it to electrolytic action indirectly due to the fact that the belt pulley, or equivalent member, is sitting too tightly on the shaft.

Data on evaporation tests with pressed peat and peat coke as values are reported in an abstract from a German publication. Also from a German publication is taken an abstract of tests on the mechanical properties of teak wood.

From the Memoirs of the College of Engineering of the Kyushu Imperial University at Fukuoka, written in German, is taken the abstract of an investigation on the bending elasticity of cast iron, of considerable interest because of the lack of reliable information available on the behavior of cast iron under either tension or bending.

A paper by H. C. Richardson, on hulls for aeroplanes brings us into a comparatively new field of research. The author indicates the essential points of difference between aeroplane hulls and what he calls "boats working in ordinary displacement conditions." The subject of the action of suction on a boat travelling through, and perhaps out of water at high speed has been investigated thoroughly and important conclusions as to the water resistances arrived at. It appears further that a form of hull has been devised for the navy, having decided advantages over those already in use, so far as resistance on the surface and in the air is concerned.

The subject of motor cylinder lubrication is discussed by G. S. Bryan, U. S. N., in a paper before the American Society of Naval Engineers. Among other things, the writer shows that what is generally known as carbon deposits in the cylinders, does not as a rule essentially consist of carbon. He shows further that the flash point of lubricating oil, while important, does not affect the possibility of the oil adhering to the cylinder walls to the extent often assumed.

Two papers of undoubted value are printed in the journal of the American Society of Refrigerating Engineers, by H. C. Dickinson and N. S. Osborne, of the Bureau of Standards at Washington, D. C. One concerning an aneroid calorimeter, in which copper acts as a calorimetric medium for the transmission and distribution of heat, such calorimeter having several important advantages over the usual stirred water apparatus. The other paper contains data of painstaking investigation of the specific heat of ice, especially near its melting point as well as corrected values for the heat of fusion.

J. Irving Lyle, in a paper on air conditioning (Engineers Club of Philadelphia) illustrates the wide possibilities of applying the control of temperature in industrial plants (bakeries, candy factories, printing establishments, etc.) and the great hygienic benefits which can be secured by it.

A series of tests made to determine the type of coating best suited for the protection of metal imbedded in concrete against the action of electrolysis, as well as the bond between concrete and painted metal are described by Henry A. Gardner, (Franklin Institute) and among other things, the author describes a method of increasing the bonding between the metal and cement by applying to the painted surface while still tacky, sharp particles of fine clean white sand, thus forming a rough surface resembling coarse sand paper.

The interesting subject of the production of oils from peat is treated by Dr. F. Mollwo Perkin (Institution of Petroleum Technologists). While the author is by no means sanguine as to the commercial possibilities of such a production, he does not consider the difficulties in its way insurmountable.

The calculation of centrifugal stresses in turbine rotors forms the subject of a paper by William Kerr, before the Scientific Society of the Royal Technical College, Glasgow. Only the parts concerning solid shaft rotors and hollow shaft rotors are abstracted in the present issue. The second

part of the paper will be abstracted in an early issue of The Journal.

The timely subject of the high speed, high efficiency eight cylinder V-Type engine is discussed by D. McCall White, who is responsible for one of the earlier American automobile engines of this type, before the Society of Automobile Engineers. As compared with the former four cylinder engine, the eight is about equal in length, is only wider by 2 in., weighs from 50 to 60 lb. less, uses a short 4-throw crankshaft and is expected to outlast considerably even an equally well designed and made six.

Interesting tests on high speed steel drills are reported in a paper on High Speed Steels, by Fred C. A. H. Lantsberry (West of Scotland Iron and Steel Institute). Among other things, he found that the efficiency of steels as drills increased to maximum when the content of tungsten rose to 14 per cent and then fell off with further increases in tungsten. Vanadium in small quantities proved to be useful, but steel containing one per cent of vanadium above the quantity eliminated in manufacture, was found to be of absolutely no use for drills.

FOREIGN REVIEW

Air Machinery

ACTION OF AN AIR JET ON THE SURROUNDING AIR

The article is an abstract of a university thesis based on experiments carried out in the mechanical laboratory of the Technical High School in Karlsruhe, and proposes to investigate the loss of concurrent motion of surrounding air produced by a jet of air flowing through a nozzle.

When a jet of air discharges from the nozzle of a blower into the free atmosphere, a part of its energy of flow is transferred to the surrounding air, the friction between the various layers of air acting as a medium of transmission. What the author investigates is

- a The shape which the stream assumes after its discharge from the nozzle.
- b The exchange of energy between the active nozzle stream (core stream) and the passive stream of the surrounding air carried away by the active stream (jacket stream).

The article describes in detail the experimental installation and method of tests and then proceeds to the discussion of the results obtained. The velocity curves, which he denotes as $c-r$ (compare Fig. A), where c is the velocity of air and r is the radial distance of the point of measurement from the axis of the air jet. Such $c-r$ curves as have been obtained indicate a rapid decrease of the velocity of jet with the increase of the distance from the nozzle. Immediately at the exit the velocity curve (1 in Fig. A) is practically a horizontal line, that is, in all points of this cross-section the velocity of air is equal. In the next cross-section investigated ($x = 20$ cm.) this uniformity of distribution obtains only within a certain area, the diameter of which is equal approximately to one-half the diameter of the nozzle, and the air lines on the outer edge of the jet and in its neighborhood have already lost a considerable amount of their velocity. The next curve has no longer any straight section at all.

From the $c-r$ curves, the author develops the volume

curves by means of the following process. He assumes that the cross-section of the nozzle is a circle and that at each cross-section at points of equal distance, r , from the axis of the jet, the velocity of air c is equal; then for an infinitely thin ring of thickness dr the volume of air flowing through it per second is expressed by $dV = 2\pi r c dr$, and, therefore, the volume of air flowing per second within a circle of radius r

is $V = 2\pi \int_0^r c r dr$. This integral can be solved graphically by means of the $c-r$ curves found experimentally; it is, however, not the velocity curve itself but rather the curve derived from it, $cr-r$, that has to be integrated.

The product cr can likewise be found graphically, but it is more convenient to determine it by calculation, (the author gives a special table to facilitate this), and then plot it graphically over r as abscissae. The curves of integration obtained from the $cr-r$ curves (Fig. C) then give for each cross-section a definite volume corresponding to each value of r , this volume indicating how much air flows per unit of time through a circle corresponding to the given r , while the terminal point of the curve, by its ordinates, indicates what total volume of air per second passes through the cross-section of the jet. The graphs in Fig. B show that with the increase of the distance from the nozzle, the terminal point of the crowd of curves which start originally like an S , gradually diverges in a diagonal direction, always farther and farther away from the zero point, showing thereby that as the distance from the nozzle increases the radius of the entire jet of air, as well as its volume, increase also. If the radii were plotted as ordinates over the x 's of the axis of the nozzle (there corresponds to each curve and value, a definite distance of cross-section) the $c-r$ would indicate the extreme meridian line of the jet.

It would be of still greater interest to plot on the same system of coordinates those values of r which correspond in the various sections of the jet to equal V . The plotting of such values on the $c-r$ system gives a nearly exactly straight line. It appears, therefore, that the active core stream expands conically. By this method of handling the volume curves, the author creates a clear conception of the location of meridian lines limiting the passive jacket stream. From this, he passes to the determination of the amounts of energy contained in the various parts of the jet.

The transmission of energy between various layers of air at different velocities may be also determined graphically from the velocity curves found above. The kinetic energy carried by air volume dV , passing per second through an annular area of thickness dr is

$$dE = \frac{c^2}{2} dV = \frac{\gamma}{g} 2\pi r c \frac{c^2}{2} dr.$$

The latter because $dV = 2\pi r c dr$. Hence the energy of the volume of air which flows through a circular cross-section of the radius r_k is

$$E = \pi \frac{\gamma}{g} \int_0^{r_k} c^3 r dr.$$

By r_k in each cross-section under investigation is understood that value of r which is found by the process described in the preceding paragraph for the gradual increase in the friction of the jet of radius of the active core stream. Hence, the integral gives the amount of energy contained in the respective sections of the core stream. If it should be integrated now up to the value of r , corresponding to the velocity $c = 0$ or

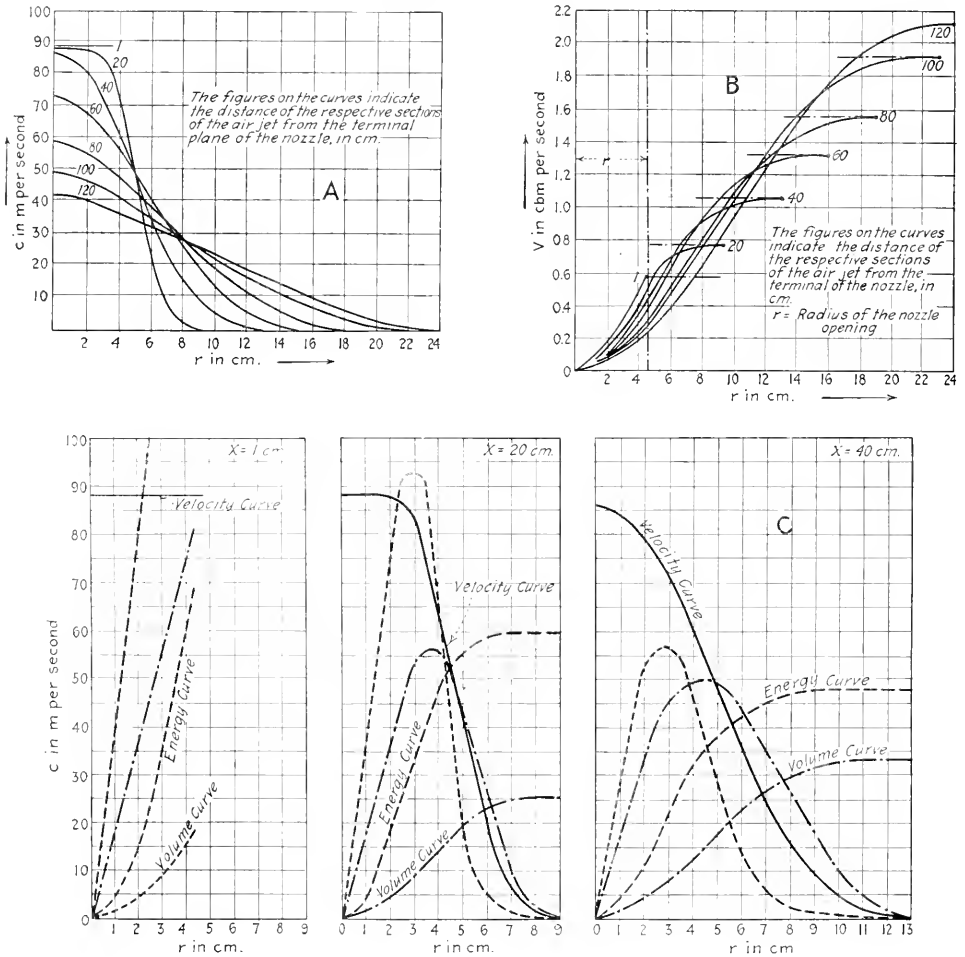

FIG. 1. ACTION OF AIR JET ON THE SURROUNDING AIR

A. Velocity curves ($c-r$); B. Curves of volume as function of distance from nozzle ($V-r$); C. Volume curves and curves of integration of the $c-r$ curves; D. Energy curves for total jet and core jet

up to the limit of the jet, we obtain the total energy of the moving stream of air. The difference between the two integral values, that is, the difference between the energy of the total jet and that of the core stream, represents the energy in the jacket stream.

For purposes of graphical solution, the numerical values of $c \cdot r$ are calculated and plotted as ordinates over the values of r as abscissae; then an integral curve is constructed for the $c \cdot r$ curves thus obtained. We obtain here again S-shaped curved lines which start, like the volume curves, from the region of coördinates. Contrary to those latter, however, the terminal point of the distance from the nozzle approaches nearer and nearer to the r axis, while in the course of flow the volume increases as the energy contained in it constantly

decreases, more and more. Now if these values of energy be plotted over x as abscissae, each on the E - x curves belonging to the limiting value of r_k and of r , which corresponds to the velocity $c = 0$, we obtain two series of points of which one represents the variation of energy in the active core stream and the other in the total stream (Fig. D). At the opening of the nozzle, in both of them, the decrease of energy is maximum, but with the increase of distance from the nozzle, the amount representing the decrease of energy, either in the core or the total stream, becomes smaller and smaller as indicated by the decreasing inclination of the curves. Finally, the value of energy must sink to zero, which happens for both curves at the same value of x . Experimentally the investigation could not be carried to this point.

The energy curves of Fig. D, obtained from the above experiments, indicate in particular that the energy in both cases falls off very rapidly and that the larger part of the energy contained in the jet is not carried away by the latter but is wasted on the way through friction and eddy formation. Even at a distance from the nozzle as little as $x = 60$ cm. the amount of energy contained in the inner stream was only one-half of the energy which the stream had as it left the nozzle. This loss of kinetic energy ought to be compensated for by an increase in some other form of energy; in this case, the increase in temperature. This could not be established experimentally, however, both because, as the author shows by calculation, such an increase in temperature would be very low and especially because this measurement in the rapidly flowing air is extremely difficult.

From this, the author proceeds to the determination of the coefficient of friction. The article contains several tables of data obtained from these experiments; among others, values of velocity of air, mechanical value of constants in the equation of curves $cr-r$ and c^3r-r . Computation of the friction coefficient R and the table for converting the values of R given in engineering units to r (expressed in e.g.s. units). (*Über die Einwirkung eines Luftstrahles auf die umgebende Luft*, Dr.-Ing. Theodor Trüpel, *Zeits. für das gesamte Turbinenwesen*, vol. 12, nos. 5 and 6, pp. 53 and 66, February 20 and 28, 1915, 10 pp., 13 figs. et).

Hydraulics

ELECTRICAL METHODS OF TESTING HYDRAULIC TURBINES.

The guarantees given nowadays by manufacturers of hydraulic turbines are very strict and it is therefore of importance to have a convenient method for testing them, especially when in very large sizes. The author recommends to test electrically machinery driving electric generators, and describes a method for determining by means of very simple apparatus the losses and efficiency of alternating current generators and driving machinery coupled with it. He discusses in particular a case where a single phase synchronous generator was directly connected with a Pelton turbine provided with ellipsoidal blades and needle nozzle. The losses of the machinery, either electrical or hydraulic, were not previously known. The exciting current was in one instance taken from a separate source and in another, from an exciter generator driven by a belt from the main turbine.

With the water turbine (quantity regulation), the useful output varies, as experiments have shown, in the lower part

of the curve, as a straight line function of the water volume and in its upper part, either as a straight line or as a line slightly curved (according to circumstances), the assumption being that the speed is constant and that at the turbine inlet there is a constant water pressure. The point of intersection with the axis of abscissae can be easily determined by measuring the water consumption of the turbine with the generator uncoupled. The lower section of the line of output has at first been assumed arbitrarily, starting from the no-load point of intersection (curve a , Fig. 2A). The turbine can now be temporarily considered as a calibrated motor and the no-load and short-circuit load of the generator can be determined with *first approximation* by means of this N_m line. These losses are shown in Fig. B as "1 results" curve. Next, a series of tests was carried out by varying the loads, and the useful output of the turbine N_m was determined on the basis of the output measured and the generator losses previously found (curve b , Fig. A). The exciter losses were not considered in this connection because they were taken care of by a separate machine. The fact that N_m line found with these load tests did not coincide with the line previously assumed shows that the line a was evidently taken too low. The friction, iron and copper losses, as found in the first four series of tests, were now corrected on the basis of the curve b , and the useful output of the turbine, as obtained from the load tests, changed in accordance with the corrected generator losses, this giving curve c in Fig. A. It must be pointed out in this connection that the tests themselves did not have to be repeated; only the calculation is repeated, and even this applies only to two or three small loads or losses. Curve c gives another basis for correcting the iron and copper losses. It is, however, clear that within the region used for the determination of the losses, the curves b and c would practically coincide provided the assumed curve a is not too far from actuality. This assumption may be made, for example, on the basis of the guaranteed efficiency of the manufacturers. This method is apparently nothing but the "regula falsi" applied to engineering measuring.

In connection with the carrying out of these tests, the following may be of interest:

First. The measurement of the volume of water was made by means of overflow with lateral contraction. Previous to the test, it was calibrated by means of a reservoir and points on the curve were taken for quite small amounts of water. It was found that the Fresse coefficient of overflow agreed best with the experimental data.

Second. The head of fall was measured by a precision manometer in front of the turbine inlet. The fall was maintained constant by means of a slight throttling by a gate valve, located in the pipe somewhat to the rear.

Third. A constant speed of rotation was maintained by adjusting the needle of the nozzle with a hand wheel until the tachometer indicated the desired speed.

Fourth. The alternating current produced was converted into heat in a non-inductive water-cooled wire resistance. The output as indicated by the watt meter was very nearly equal to the product of current voltage.

Fifth. With direct current, cold, the resistance of the armature winding was 0.026 ohms, while the direct measurement of the copper losses showed an effective resistance of 0.07 ohms, the difference being due to additional eddy cur-

rent losses and to the rise of temperature in the armature copper. These additional losses are taken care of by a corresponding increase in the value of the direct current resistance. Had they been neglected, it would have led to an error of considerable magnitude. With a load of 126 amperes, the difference would have been 0.7 kw., equivalent to an estimation of the efficiency of the turbine about 3 per cent too low. It is worth while to note that it appeared that the effective resistance of the armature increased with the smaller current, due to comparatively large iron losses at short-circuit in this particular machine.

Sixth. The electromotive force at load was calculated in the following manner. The total excitation field at load, which has to be applied as composed of the resultant field and short circuit field, in the present case expressed in terms of excitation current, is $i^2 = i_k^2 + i_r^2$. The short circuit characteristic (Fig. B) gives the short circuit exciting current i_k corresponding to each armature current J . From the short circuit exciting current i_k and the exciting current i , measured on load, can be calculated the excitation component corresponding to the resultant field $i_r = i^2 - i_k^2$

FIG. 2

A. Output and efficiency of free jet turbine at constant head; B. No-load and short-circuit characteristics of single-phase generator ($n = 375$ r. p. m.).

and the emf on load which belongs thereto can now be taken direct from the no load characteristic of Fig. B. If instead of this emf on load be used the terminal potential, this will lead to establishing the generator losses as being too slow and hence the efficiency of the turbine will appear too low also. In this case, however, the error is usually small and amounts at maximum load to only about 0.6 per cent against the turbine efficiency.

In tests of large turbines it is not always possible to regulate, in a simple manner, the water resistances so as to obtain different loads at constant terminal potential. On the other hand, it is always very simple to get any load, however small, by exciting for small voltages with constant water resistance. If both methods of varying the load are practicable, a means of control of measurement of the generator losses is thereby additionally provided.

The efficiency of the turbine in the tests carried out by the author has been found comparatively small and he remarks in this connection that from full load to half load, it is 80 per cent, if the turbine is driven at its best speed of 500 r.p.m. with the designed head of 42.8 m. (140.3 ft.). The low efficiency may also have been due to the fact that the turbine and generator were not built for the same normal output (turbine for 16 kw. and generator for 20 kva.).

If the main turbine is to drive in addition to the generator the exciter also, the electrical measurements may be carried out in the same manner as above described, but the output of the exciter has to be determined by a separate series of tests. Such a test might have been carried out with the same apparatus as indicated above, a d.c. generator being driven from the turbine shaft by a belt. In the first place, one has to determine the losses of the exciter at no-load. After that, the exciter losses are determined separately and subtracted from the respective outputs of the first series of tests so as to determine the iron losses. This, however, requires the cutting out of the generator excitation in the second series of tests. To do this, the generator is uncoupled and the rotor set out of motion thereby. Then the field windings serve as a load resistance to the exciting current. In many cases where this cannot be done, it is necessary to have the exciter operate on a separate load resistance. Another method might be to repeat the first series of tests with separate excitation. This would give at once the iron losses and the exciter losses would appear as the difference between these outputs and those of the first series of tests.

A method of measuring water by overflow used in the present tests proved to be extremely convenient and exact. In water power plants it is not always applicable, especially where the volumes of water are very large, in which case they have to be measured by vanes. In this case, the loss measurement of the turbine output may be determined as a function of some geometric magnitude, for example, servometer stroke or indicator position. The measurement of water volume may then be limited to definite tests of output. For exact measurements of the losses it must be assumed that the fall remains constant within the region of outputs used for the determination of losses, and it is also assumed that it is possible to read the indicator with absolute precision; that means that the scale has fine divisions and that there is no lost motion. Since, however, the connection between the indicator scale and water volume is not a linear one, a large number of the points at small outputs must be plotted in load tests so that the curve N_m line could be plotted as a function of indicator positions with sufficient clearness. (*Über Leistungsmessungen an Turbinen auf elektrischem Wege*, Dipl.-Ing. A. Strickler, *Bulletin, Schweiz. Elektrotechnischer Verein*, vol. 6, no. 3, p. 33, March 1915, 8 pp., 7 figs. ed).

Internal Combustion Engineering

BELLEM AND BRÉGÉRAS AUTOMOBILE ENGINE

The article describes an improved type of the Bellem and Brégéras engine.

A special characteristic of the Bellem and Brégéras engine is that it can use, without preheating, even the least volatile fuels and can start on ordinary kerosene. In order to attain this important result, the inventors have had recourse to the use of injection and to atomization under very strong suction. At each suction, a certain amount of liquid is carried by a pump into a special atomizing valve which opens only after the piston is down a certain part of its stroke, creating a considerable vacuum in the cylinder. Immediately after this, carburetted air is admitted, the rest of the cylinder volume being filled up with pure air through a second admission valve.

The difficulty which the inventors encountered at first

FIG. 3. BELLEM AND BRÉGÉRAS ENGINE

A, engine piston; B, atomizing valve; C, air admission valve; D, exhaust valve; E, rod of the pump piston; F, cylinder; G, cork protector; H, upper thrust block which can be governed by I and is connected with the air valve, J. (The pump takes in air at the bottom of the stroke, while the delivery occurs when the cylinder touches G and lifts it off its seat.)

was as to how to regulate efficiently the speed of the engine. In the original engine, this was done by a rather complicated device involving the use of a mercury column. In the present type shown in Fig. 3, this mercury column is eliminated and the regulation is effected by the construction of the feed pump which has a variable speed. As shown in the figure, it is of a reciprocating type with a plunger piston actuated by a connecting rod and eccentric, the cylinder centered about the piston with no connection to any fixed piece. Instead of any packing glands, there is a cork protector, which produces considerable friction between the cylinder and the piston. If not limited, the cylinder adhering to the piston, would move up and down with it without producing any pumping. Actually, however, two thrust blocks limit the motion of the cylinder, which latter naturally has to be deduced from the effective stroke of the pump.

(*Perfectionnement au moteur Bellem et Brégéras*, A. W. Omin, no. 445-28, p. 18, July 11, 1914, 1 p. 1 fig. d.)

By varying the distance between the thrust blocks, one can vary the freedom of motion of the cylinder and thereby the effective stroke and output of the pump. It is very simple, of course, to change the distance between the thrust blocks and that is all the regulation which the new Bellem & Brégéras engine requires.

Mechanics

LATERAL FLEXURE OF HOLLOW PIECES, Henry Lossier

The article discusses the subject of lateral flexure of hollow pieces and shows how errors in calculation may be made in this connection.

Metal or reinforced concrete constructions often involve elements under compression, constituted by two parallel members A, united at equal intervals by cross-pieces B, so as to form a rigid structure. Fig. 4M shows, for example, an iron structure in which the members A consist of channel irons and B, Fig. N, of double pieces of sheet metal. In Fig. O, the members are angle iron and the cross-pieces, sheet metal, crossing each other at right angles. In either case, each unit carries with it at least two rivets. Fig. R shows a hollow element of length L, containing four equal rectangles and being under the action of an axial compression P.

It is usual to compute the stresses on such an element by considering it as being similar to a solid prism having the same moment of inertia and then taking its resistance to lateral flexure as being equal to that of a trunk or length f, taken between two consecutive cross pieces. Such a method of computation which would be all right if the cross pieces were supplemented by diagonal members (indicated in Fig. R by dotted lines), would be correct for this case only if the flexure of the element occurred as indicated in Fig. S, that is, with the axis remaining rectilinear all through the deformation. Actually, however, the flexure will occur by a lateral bending of the axis, as shown in Fig. T.

Because of such a deformation the following takes place:

- The normal stresses, of which the initial value for each member is $P/2$, undergo a decrease in the convex member A' and a corresponding increase in the concave member A. This effect has its maximum value in the central trunks 2-2'.
- Because of the absence of diagonal stays and rigidity of the structure, secondary flexures occur both in the members and cross-pieces; these flexures, which are functions of the shearing stresses, reach their maximum values in the end trunks 1-1'.

The author recommends, therefore, for the calculation of such elements, the following formula and states that the fatigue of members will increase indefinitely as long as the stress P exceeds the critical value of P_c equal to

$$P_c = \frac{\pi^2 EI}{L^2} \left[\frac{\alpha}{1 + \frac{I + 2I_A}{2.5u^2 I_A} \alpha} \right]$$

where E is the modulus of elasticity of material, L length of flexure, I_A the moment of inertia of the member A, I the moment of inertia of the entire element,—that is the two

members, A, $u = \frac{L}{f}$, α is a variable coefficient which is a function of the number of sections u, and has the following values:

$n = 2$	3	4	5	6	7	8	∞
α	1.62	1.22	1.11	1.07	1.05	1.04	1.03	1.00

This formula is not new and its first member is simply the Euler formula, giving the bending resistance of a solid prism having a moment of inertia equal to I . The second part, which will be referred to later on as k , has a coefficient smaller than unity, towards which it tends as the number of sections increases, so that for $n = \infty$, $k = 1$. In other words, k represents the ratio of the resistance of a hollow prism to that of a solid prism. The author recommends, therefore, the adoption of the following rule: *in a piece under compression, consisting of two parallel members connected into a rigid structure by cross-pieces located at equal distances from one another, the coefficient of permissible work is equal to the coefficient for a solid prism of the same moment of inertia multiplied by a coefficient k , less than unity, and given by the formula*

$$k = \frac{\alpha}{1 + \frac{21}{2.5n^2} \frac{I}{A} \cdot \alpha}$$

From a numerical example, the author obtains curves

FIG. 4 LATERAL FLEXURE OF HOLLOW PIECES

shown in Fig. W, in which he uses for the upper curve (ordinary method) the Euler formula; next, the full drawn out curve represents what he would obtain with the formula proposed in this article, and finally the third curve is obtained by the Timoshenko formula (Annales des Ponts et Chaussées, May-June 1913), which the present writer uses in the form

$$P_{cr} = \frac{1}{\frac{L^2}{E I \pi^2} + \frac{f^2}{24 E I A}}$$

obtained by neglecting the deformation of the cross pieces. This figure shows that with the exception of very small values of n , it gives results fairly close to those obtained by the Timoshenko formula which apparently tends to prove its correctness, as the Timoshenko formula is one of late date and apparent reliability. (*Etude du flambage des pièces comprimées*, Henry Lossier, *Le Génie Civil*, vol. 66, no. 10, p. 150, March 6, 1915, 2 pp., 8 figs. t).

BALL BEARINGS, Prof. J. Fischer-Hinnen

Investigation of the relation between axial and radial load on ball bearings.

Fig. 4 shows the state existing in an axially loaded bearing in a somewhat exaggerated manner. R is the radius of the tread, r radius of the balls, and $2a$ maximum distance between treads. It is further assumed that the distance $2a$ is by α per cent greater than the diameter of the balls, that is

$$a = \left(1 + \frac{\alpha}{100}\right) r$$

and therefore, because of the axial pressure P_a there appears a pressure component, directed normally to the balls, P_n of the magnitude

$$P_n = \frac{P_a}{\sin \beta}$$

The author further shows that the relation between P_n and P_n is determined by the following equation

$$P_n = \frac{2.2}{\sqrt{\alpha}} P_a$$

where 2.2 represents a coefficient which varies somewhat for different kinds of bearings (the author gives a table showing

that), but may be taken to be equal to 2.2 for general purposes. This equation permits the determining of the additional pressure P_n when the axial pressure P_a and play α are known, and gives very interesting results. Thus, if the play is as large as 0.5 per cent, and the axial pressure is one third of the radial pressure, then

$$P_n = \frac{2.2}{\sqrt{0.5}} \cdot \frac{1}{3} = P$$

or the additional pressure is about 100 per cent of the radial pressure. Since, however, the manufacturers guarantee considerably smaller play, much greater additional pressures have to be looked for.

In the above connection, the author calls attention to the pitting to which the shaft on which a ball bearing is running is often subject, and which results in a surprisingly rapid wear of the shaft. Even though the gripping of the races against the shaft has been eliminated, very great wear of the shaft is nevertheless often the fact. It might have

been possible to ascribe it at first glance to the compression of material, but the low specific pressure at which ball bearings are run and the peculiar appearance of the surface of the shaft, which in places looks rusted and pitted, are against such an assumption. The author claims to have seen exactly similar conditions on shaft journals of engines not equipped with ball bearings and in which, after a run of only four or five hours, there appeared large rust spots and pits $\frac{1}{10}$ mm. deep.

In all of these cases it was found that the belt pulley was sitting pretty tight on the shaft. It would appear, therefore, that the cause of the wear of the shaft was electrolysis. In nearly all cases in which this phenomenon was observed, the engines were standing normally to the earth's meridian; that is, normally to the magnetic field of the earth, which, however, is not absolutely necessary for this effect because stray magnetic fields pass through the shaft anyway. It would appear, therefore, that in the boss, alternating current is generated. Since, however, the boss, because of its wedging, can have only a tilting motion in two directions,

FIG. 5 INFLUENCE OF PLAY ON DISTRIBUTION OF STRESSES IN A BALL BEARING

there is, synchronously with the variation in direction of current, also a variation in the contact resistance; that is, the resistance at one change of direction of current is minimum and at another change is either maximum or infinite. We, therefore, have before us a kind of current rectifier which explains possible electrolytic action. If, on the other hand, the boss is loose on the wheel, both directions of current act at the same time and therefore there is no electrolysis. The same is the case with the races and ball bearings, and that is what this occasional excessive wear is due to. (*Über Kugellager*, Professor J. Fischer-Hinnen, *Elektrotechnik und Maschinenbau*, vol. 33, no. 12, p. 141, March 21, 1915, 2 pp., 3 figs. tp).

Steam Engineering

EVAPORATION TESTS WITH PEAT AND PEAT COKE AS FUELS.
H. Winkelmann

Report of evaporation tests with peat and peat coke, carried out on saturated steam locomobile and fire tube boilers.

The engines were used to drive peat-making machinery and were designed accordingly. The boiler, designed like a locomotive boiler, was equipped with a large box-shaped fire box, similar to the so-called Colonial locomobile boilers for burning straw, sugar factory refuse and corn stalks. The grate was designed suitably for this kind of fuel and very generously proportioned. Since the peat can be burned with comparatively small amounts of air [theoretically 4.9 lb. per lb. of peat at 15 deg. cent. (59 deg. Fahr.) and 73.5 en.

barometric stand., with ignition temperature between 220 and 240 deg. cent. (128 to 464 deg. Fahr.) and temperature of combustion about 800 deg. cent. (1472 deg. Fahr.)], the free grate area is kept pretty low, so as to have as little excess of air as possible. In fact, with peat, it amounts to only 1.8 times to twice the theoretically required amount of air, just as with other kinds of boilers in which fuel of low heating values (and therefore in large amounts) is used, and particularly large fire doors are here provided. Data as to the fuel are given in Table 1.

The tests, full data of which are contained in the original article, have shown that even when pressed peat is used, with a comparatively high content of moisture, it is quite possible to obtain a boiler efficiency (referred to the fuel burned) of 60 to 62 per cent and this efficiency rises to 67 or 68 per cent when peat coke of much higher heating value is used. In tests where peat coke was used, the grate was reduced in accordance with its heating value. There is no doubt, however, that still better results would have been obtained if it had been possible to raise the grate duty still higher. On the other hand, however, the good burning of the fuel may be explained by the comparatively low rate of combustion.

TABLE 1 ANALYSIS OF PRESSED PEAT AND PEAT COKE

Kind of Fuel. No. of sample, . . .	Pressed peat.		Peat coke.	
	I.	II.	III.	IV.
	lb. per cent.		lb. per cent.	
Carbon	40.3	38.2	82.2	81.8

Nitrogen	0.7	0.8	1.1	1.0
Oxygen	28.4	30.4	5.2	5.2
Sulphur	0.6	0.4	0.5	0.5
Water	16.0	17.6	5.1	5.3
Ash	9.8	7.6	2.8	4.1
Combustible matter	74.2	74.8	91.1	91.6
Calorific heating value in calories per kg. B.T.U. per lb.	3080	5544	3110	5598
	7128	12830	7015	12627

The author makes the following statement as to peat coke. It is a comparatively new material, produced in special coke ovens where, from each 30 tons pre-dried raw peat from 8 to 9 tons of coke are obtained, gas and tar being secured as by-products. The gas is used to heat the vertical coke retorts as well as to drive the engines, while from the peat tar are obtained gas and creosote oils, paraffine, methyl alcohol, pitch and sulphate of ammonia. (*Einige Verdampfungsversuche mit Torf und Torfkoks*, H. Winkelmann, *Zeits. für Dampfkessel und Maschinenbetrieb*, vol. 38, no. 10, p. 82, March 5, 1915, 2 pp. e).

Strength of Materials and Materials of Construction

MECHANICAL PROPERTIES OF TEAK WOOD, A. Weiskopf

The article reports an investigation of the mechanical properties of teak wood, carried out in the laboratory of the Hannover Car Company, in Hannover-Linden, Germany. The paper gives some data as to the manufacture of teak wood articles and its general properties, and then proceeds to report the data obtained from the investigation itself.

The extensive and growing introduction of teak wood for use in car construction in Germany made it desirable to obtain precise information as to its mechanical properties. The present investigation was somewhat curtailed in its scope by the coming of the war. These investigations covered compression strength, bending strength and tensile strength of the wood. For compression strength tests (Schenck testing machine) cubes 7 x 7 x 7 cm. or 10 x 10 x 10 cm. were used; for bending tests (same machine) bars 80 cm. long

and 8 x 8 cm. in cross-section; for tensile tests (Tarnogrocki testing machine) test bars 50 cm. long and 1 x 1 cm. in cross-section. All the tests were made on teak wood of two kinds, Indian and Java.

Separate tests were made on artificial drying of teak at a temperature of 50 deg. cent. for periods up to 40 days. The results obtained are tabulated in the original article and show that the loss in weight for a period of drying of one day amounted to 2.3 per cent. Then for the next two or three series of two to three days each this loss varied from 2 to 2.8 per cent, with a considerable decrease in the later stages of drying, so that in the last ten days of the test, it amounted only to 1.2 per cent, the total loss in weight after 40 days being 15.7 per cent. As regards the change in volume, no change was found in the length (in the direction of fibre, but parallel to the year rings), but 1.4 per cent was found in the width (tangential to the year rings), and 1.1 per cent in thickness (radial to the year rings).

The data of compression tests are given in the original article in the form of a table and two curves, one for Indian and another for Java teak. This table is not repro-

FIG. 6 BENDING TESTS ON INDIAN TEAK WOOD

duced here. There the stress in compression was applied in three directions, that is, in the direction of the fibre; normally to the fibre and radially to the year rings, and finally, normally to the fibre and tangentially to the year rings. It was found that the Java teak is stronger in compression than the Indian teak and can stand stresses as high as 479 to 498 kg./qcm. For the sake of comparison, the author quotes several kinds of other European woods, such as oaks, with a maximum strength of 327 kg./qcm, and foreign woods, Jarrah 321, Bongosi 599, Njabi 503 and Bang 444 kg qcm. (the last three are grown in Kamerun, Africa).

The bending tests have been carried out on the same machine as the compression tests; their data are reproduced in a table and again in two sets of curves, of which the curves in Fig. 6 for Indian teak are here reproduced. The axis of the abscissae indicates loads in kilograms and the ordinates, bending in millimeters. In curve I, at the load of 500 kg., there is a deflection of 1 mm., while at 3000 kg. the deflection is already as high as 11 mm. At point a the maximum stress is reached, at a breaking load of 3450 kg. At that point the test piece is ruptured, as is indicated by a loud crack.

In addition to that, with the pressure radial to the year

rings, the upper part of the wood in one of the year rings on one-half of the test bar became loose, so that the lower part of the bar appeared, at the conclusion of the test, to be pushed out forward. Next we see a brief backward run of the line; then a further bending of the bar and finally a longer backward motion of the line up to point b, to which corresponds a load of approximately 1720 kg. From here on, the test bar again becomes able to take up a larger load, which gradually rises at point c to about 2290 kg., after which a new backward motion of the line begins. As far as the useful strength of the wood is concerned, the diagram is of importance only up to the point a, but the rest of it is also of interest for the estimation of the quality of the wood in as far as it shows that the test bar, even at maximum load, does not break down entirely, and that rather only a part of the fibre is destroyed, while the other part still holds together and offers further resistance.

The results of tensile strength and rupture tests are reported in a table, both for Java and Indian teak wood. Such tests are rather hard to carry out because there is considerable difficulty in the preparation of the test bars, as it is difficult to cut them in such a manner that in the reduced cross-section bar the longitudinal fibres run parallel to the longitudinal axes. No tests have been made on the behavior of the wood under sand blasts. (*Untersuchungen von Teakholz in der Hannoverschen Waggonfabrik A.-G., Hannover-Linden*, Dr. techn. A. Weiskopf, *Glaser's Annalen für Gewerbe und Bauwesen*, vol. 76, no. 4, p. 68, 904, February 15, 1915, 7 pp., 8 figs. e).

FIG. 7 ELASTIC PROPERTIES OF CAST IRON

BENDING ELASTICITY OF CAST IRON, Professor Akimasa Ono.

The article presents data of tests on tensile, compressive and bending strength of cast iron, and discusses the bending elasticity of cast iron. It also treats of the permanent set produced in cast iron by bending as well as the relation between the elastic and permanent sets in bending or tension. In his introduction, the author briefly summarizes the results of preceding investigations of Kármán, Bach, Pinegin, Herbert and Schöttler. The tests were carried out in the machine laboratory of the University of Fukuoka, on a 13,000-kg. Mohr and Federhaff testing machine.

The data of the tensile and compression tests are presented by the author in a number of tables. Among other things, he found that both the total and the permanent elongation, occurring at a certain stage of loading, materially increase with the number of repetitions, while the elastic elongation appears to have a much more regular behavior. Tables 2 and 3 respectively give a compilation of results obtained

from four tests each. If the equation $\epsilon = \alpha \cdot \sigma$ is used, in order to present the relation between σ and ϵ , one obtains from the above experimental data the following equations:

For tensile strength:

$$\epsilon = \frac{1}{2690700} \cdot \sigma^{1.193}$$

and for compression strength:

$$\epsilon = \frac{1}{1320800} \cdot \sigma^{1.049}$$

The author shows that the curves obtained from these equations nearly coincide with a curve obtained experimentally, the latter representing a purely elastic behavior of the material investigated.

From this, the author proceeds to explain his method of calculating the bending moments from the data of tensile and compression strength tests. He has also made a number of bending tests on test bars prepared from the same piece of cast iron from which the samples for the tension

during the bending test was considerably slighter than during the tension test. To illustrate this fact, two curves (Fig. 7) were plotted, showing the relation between the elastic and permanent elongation in tension and bending, and the comparison of these lines indicates the presence of an initial stress as well as the rise of additional stresses. Strictly speaking the data of tests, both on elasticity and on strength generally, cannot be clearly understood without taking into consideration these internal stresses.

Finally, the bending tests have confirmed the statement made by Schöttler to the effect that the permissible bending stress, k_b , is to k_z (permissible stress in tension) in a ratio different from $\frac{K_b}{K_z}$ (strength in bending and tension, respectively). (*Die Biegeungselastizität des Gusseisens*, Professor Akimasa Ono, *Memoirs of the College of Engineering, Kyushu Imperial University, Fukuoka, Japan*, vol. 1, No. 2, p. 111, 1915, 54 pp., 13 figs. te).

TABLE 2 VALUES OF σ AND ϵ FROM FOUR TENSION TESTS

σ kg/cm ²	ϵ (observed) 10 ⁻⁴	ϵ (calculated) 10 ⁻⁴	Difference between calculated and observed values	
			10 ⁻⁴	in per cent of observed elongation
95.5	0.900	0.856	-0.044	-4.9

389.2	3.918	3.947	+0.029	+0.7
486.5	4.998	4.988	-0.010	-0.2
583.8	6.028	6.039	+0.011	+0.2
681.1	7.148	7.100	-0.048	-0.7
778.4	8.213	8.167	-0.046	-0.6
875.7	9.283	9.241	-0.042	-0.5

and compression tests were taken. In the preparation of all these samples, great care was taken to obtain a sound casting. The method of carrying out the test and the arrangements for taking fine readings is fully explained in the original article and the data of tests given in tables.

The author finds that the law $\epsilon = \alpha \cdot \sigma^m$ is not so fully adhered to in tension as to permit its being used for a reliable expression of the elastic behavior of the material investigated. He also found that the constants α and m , in the above equation for elasticity, are different from those which Bach found for various test bars made of cast iron. Next he determined graphically, on the basis of the data obtained from tensile and compression tests, the relation between the moment of bending and the elongation of the extreme outward layer in tension of the bar under bending. The curves obtained in this manner were used in order to determine the elongation of the above referred to layer of fibres corresponding to every moment of bending. Naturally, however, this graphically determined elongation did not fully coincide with that actually observed probably because of unequal cooling of the metal.

A very remarkable fact was found that the permanent elongation observed in the extreme fibres and under tension

Hulls for Aeroplanes, H. C. Richardson, U. S. N. (abstracted)

HULLS FOR AEROPLANES, H. C. Richardson

The paper reports tests on various hulls for aeroplanes, made at the Naval Model Basin since 1911.

The conditions of operation of aeroplane hulls are materially different from those met with in ordinary displacement work. In the first place, the speeds at which these hulls are used are very high,—from 45 up to and in excess of 60 miles per hour. Then, after a speed of 20 miles per hour is obtained, it is possible to control the trim of the hull so that it can be forced through the water at a different inclination than it would assume naturally. The most impor-

tant difference, however, is that while the load carried by the hull decreases practically as the square of the speed, this decrease in load is also a function of the angle of the machine with the horizontal and is, therefore, subject to change with change of trim.

The author produces several curves, together with the respective forms of the hulls, showing for typical conditions, the curves of resistance for one-quarter size models, run at various speeds. It has been found that in ordinary displacement conditions, the resistance mounts very rapidly after a speed of about 3 miles per hour, whereas the same model, run at fixed trim and displacement corresponding to speed, runs a little harder up to 3 miles per hour, but from that point on, the rate of increase of resistance gradually falls off and the resistance reaches at about 13 miles per hour, the value of 6.1 lb. as compared with 22 lb. under displacement conditions. From that on, the resistance rapidly falls off to practically nothing at 19 miles per hour, which is the speed corresponding to that at which the wings do the lifting. As regards step-type hulls and their tendency to "porpoise" under aeroplane conditions, a number of experiments have demonstrated that the ventilation of the step

propeller and would tend to nose on that account, even though the center of gravity was placed sufficiently far behind the center of buoyancy to give a righting couple equal to the nosing moment of the thrust of the propeller when planing. This is what happened, but subsequent experiments showed that the reason for the nosing was due to the "heavier tail" and to the fact that the center of pressure under way was so near the stern that it was behind the center of gravity and thereby caused the model to nose. Many experiments with different shaped bows, flat, concave, convex and one of a freak corrugated type, showed that the shape of the bow could be varied in a wide range without seriously affecting the resistance.

An experiment was made to determine whether two models run as catamarans interfered with each other and it was found that at moderate speeds, the interference was slight and unimportant while at high speed there was practically none. Experiments with the ordinary Curtiss type and the beaver tail type showed that if the tail end of the hull was much behind the propeller position, it was impracticable to get the machine to leave the water because of the strong nosing tendency present at high speed. It was also found

FIG. 8. AN AEROPLANE HULL OF FAIR EFFICIENCY

is not absolutely necessary but very desirable, as it allows of planing at much lower speeds than is practicable if no ventilation is provided.

The first series of experiments was worked out in January 1912. One of the earliest experiments made was that with the single hull of a semi-circular section, having ogival ends. It was expected that as the resistance at low speeds was primarily due to wetted surface, which became an important factor at high speeds because of the lift of the wings, a minimum wetted surface for displacement required might give good results. This proved to be correct at low speed, but when attempts were made to run this model at intermediate and high speeds, a new effect was found and the model, instead of having its resistance decrease as the speed increased, showed a remarkable increase in resistance and a strong tendency to settle back into the water, these effects becoming more and more pronounced as the speed increased. At about 9 knots, this model tried to submerge itself and at the same time lifted sheets of spray clear of the surface of the model basin, and thus demonstrated in a very exaggerated manner the difficulties to be met with when curved surfaces are exposed to the flow of water at high speed.

In another model, this difficulty was very much reduced by trimming it at the stern, although the resistance still remained high. The model tried on an even keel and trimmed at the stern showed a behavior better than any of the models previously tried. It was predicted that in a full sized model, a sharp bow would be unable to stand the thrust of the pro-

pellor and would tend to nose on that account, even though the center of gravity was placed sufficiently far behind the center of buoyancy to give a righting couple equal to the nosing moment of the thrust of the propeller when planing. This is what happened, but subsequent experiments showed that the reason for the nosing was due to the "heavier tail" and to the fact that the center of pressure under way was so near the stern that it was behind the center of gravity and thereby caused the model to nose. Many experiments with different shaped bows, flat, concave, convex and one of a freak corrugated type, showed that the shape of the bow could be varied in a wide range without seriously affecting the resistance.

As a result, the model was run with rising fore and after body. This model behaved very well at high speeds, but the suction under the curved rising afterbody was so great as to cause excessive squatting, with the result that the propellers were brought dangerously near the water, which made this type unsatisfactory. To eliminate this difficulty, the same form of bow was used but the stern was tapered as shown in Fig. 8, this giving a sort of flat-iron stern and in order to break the suction around the stern, a step was formed at the side as well as under the bottom of the hull. This model behaved well at high speeds and satisfactory at low speeds on an even keel and on a straightaway course, but when an effort was made to turn the machine running at moderate speed, the water suddenly closed around the steps and gripped the left side of the tail of the hull. This effect grew with such sharpness that it spilled the machine over to its starboard bow and plunged the right wing into the water so that the machine was kept from capsizing only with the utmost difficulty. The above experiments emphasize the very powerful effect of suction.

As a result of the above work, a form of hull has been derived (not described) which appears to have decided advantages over those already in use in the Navy, so far as resistance on the surface and in the air is concerned.

The article contains tables showing the computation of the head resistances in water in detail for each of the models tested, as well as the frictional resistance, residual resistance and total resistance. The author comes to the following conclusions:

- a The step should be close to the position of the center of gravity, to eliminate a nosing tendency, to facilitate change of trim while planing and to avoid change of balance when getting away or landing.
- b Hollow V sections keep the spray down, cut the water more easily and cleanly, plane better, and greatly reduce shock on landing or when plunging through broken water, and practically eliminate the necessity of shock absorbers. But in practice, care must be exercised to keep this sharp keel clear on side landings or when running on the nose, as this keel tends to bite suddenly and steer strongly.
- c A shallow step is sufficient, but ventilation is essential to facilitate the breaking of suction effects.
- d The bottom forward of the step should be inclined to the axis of the machine, but
- e The inclination must not be so great as to cause planing before the controls are effective, and this is particularly necessary when running before the wind. If the planing of the hull is too pronounced, the machine rises to the surface with but very little control available to maintain balance, and when running before the wind this is more apt to occur due to the higher water speed necessary before the machine can take the air, yet sufficient reserve planing power must be available to enable planing without wing lift, or the hull will drive so hard as to be impossible to get away. These requirements are contradictory and call for a compromise.
- f The bottom abaft the step should rise strongly as this favors a steepening of the planing bow before suction is eliminated, and gets the tail well clear when planing begins. (18 pp., 9 figs. e.t.).

MOTOR CYLINDER LUBRICATION, G. S. Bryan

The article discusses the conditions under which lubrication in the cylinder of an internal combustion engine takes place and the characteristics of motor cylinder oils which determine the suitability for these conditions.

Trouble with lubrication in an engine can be traced to the following causes: poor design of engine and lubrication system, poorly refined oil, the improper supplying of oil to the cylinders, and oil of good quality but not suited to the particular type of engine. Trouble from any of the first three causes is unusual, while in the fourth case it can be easily corrected by using a different oil.

The action of heat on oils is indicated by two properties, the flash point and the fire point. It is important that the flash point shall be higher than the temperature of the

inner surface of the cylinder, as otherwise the vapor given off by the oil will prevent it from adhering to the walls. It is, however, an old theory that was never founded on solid facts that the high flash point is a necessity in the motor oil or the oil would burn up without giving any lubrication. The author claims that the point was overlooked, that when we have a maximum temperature of gas in the cylinder of 2700 deg. Fahr. and an average temperature of 950 deg. Fahr., an oil with a flash point of 450 deg. will offer a little more resistance to burning than one with a temperature of 350 deg. Either oil will burn if kept for any length of time in contact with the hot gases, but lubricating oil does not burn rapidly and the time given for it to burn in a motor cylinder is very short. A thin film of oil smeared on a hot piece of iron or steel (300 deg.) will burn for several seconds if ignited. Few motors, however, ever run at less than 120 r.p.m., and at this rate, the average point of lubricated surface of the cylinder wall would be exposed to the action of the flame for only a quarter of a second, and therefore there is no danger of all the oil film being burned in so short a time, although some of it is burned, no matter whether the flash point is 300 or 500 deg. Fahr.

A source of trouble is also the formation of carbon deposits in the cylinder, upon which subject a good deal of misinformation has been published. What is ordinarily known as carbon in the cylinders nearly always contains something else in greater or less quantity; for instance, rust and small particles of iron are nearly always found. In automobile motors a large percentage of dust is generally present and in marine motors, salt is a common constituent.

An oil that was considered unsatisfactory on account of a large amount of carbon formed in it has been recently investigated at the Naval Engineering Experiment Station and a chemical analysis of the oil from the crank casing that was supposedly full of carbon, gave results as follows:

	Per cent
Free oil	15
Water	12
Rust	11
Salt from sea water.....	58
Decomposed oil	2
Carbon	4
Foreign matter	1

Carbon may exist in a motor oil in two forms—as free carbon held in suspension or as a chemical part of the hydrocarbon compounds which go to make up the oil. Under the intense heat in the cylinder, the inner surface of the oil film is vigorously affected and in the absence of the air necessary for burning, three things might happen: *first*, the compounds may volatilize without decomposition; *second*, the compounds may decompose with the formation of free carbon and hydrogen; *third*, the compounds may decompose with the formation of other hydrocarbon compounds of a different nature. In the first case, the products will escape as gases; in the second, the carbon will be in a very fine state and be mostly blown out with the exhaust. Only when the compounds of decomposition, classed under the third case, form a gummy deposit, will the carbon stick to it and tend to make such a deposit thicker and harder and finally form the hard "carbon deposit." Where the compounds break up into new compounds, the nature of these new compounds will depend upon the properties of the oil. The oil that

will give the best results is not necessarily one that will form the least carbon but the one that will form the least carbon in the cylinders.

Oils made from Southern asphalt base crudes have shown themselves to be much better adapted to motor cylinders as far as their carbon forming proclivities are concerned, than are the paraffine base Pennsylvania oils. The carbon formed from the latter is as a rule extremely hard and clings to the metal surfaces, while that of the former is soft and can be easily wiped off any surfaces upon which it may be deposited. The cause of this lies in the fact that the paraffine oil bases are generally composed of paraffine series of hydrocarbons, while the asphalt base oils are composed mainly of the ethylene and naphthene series and one of the characteristics of these two series as compared with the paraffine series is their tendency to distill without decomposition. The lighter grades of motor oil are nearly equal in their properties, but in order to get oils with a high viscosity in the paraffine brands, it is necessary to compound the light oils in different proportions with heavier cylinder oil and it is the presence of this latter that is responsible for most of the gumming. The color and specific gravity of lubricating oils sometimes indicated in advertisements of oil companies are of no particular value to the consumer, although an expert can, from the specific gravity, in conjunction with the flash point, determine from what particular kind of crude, the straight oil is made. An Aneroid Calorimeter, H. C. Dickinson and N. S. Osborne (abstracted)

The Specific Heat and Heat of Fusion of Ice, H. C. Dickinson and N. S. Osborne (abstracted)

A Standard Basis for Finding the Fuel Economy of Steam-Driven Ice Manufacturing Plants

AN ANEROID CALORIMETER, H. C. Dickinson and N. S. Osborne.

The paper describes a special calorimeter used by the author for the determination of the specific heat and heat of fusion of ice. (See next abstract.)

The most important feature of this calorimeter is the use of a shell of copper enclosing the specimen under investigation, the copper acting as a calorimetric medium for the transmission and distribution of heat developed in an electric heating coil which is built into the shell. Temperature changes in calorimeter and contents are measured by means of an electric resistance thermometer, likewise built into the shell. The calorimeter is suspended in the air space within an enclosing metal jacket while the multiple thermo-couples are distributed about the surface of the calorimeter to indicate at any instant the difference between the average temperatures of the surfaces thus enabling the corrections for thermal leakage between calorimeter and its surroundings to be controlled and measured.

The aneroid calorimeter, as this apparatus is called, is claimed to combine the following characteristics: it is applicable to both solids and liquids, even under high pressure; the same instrument, without changes, can be used over a wide range of temperature and by suitably adapting the jacket and the liquid used therein, this range can be extended

over the region from the lowest temperature attainable up to +200 deg. cent and higher; the heat capacity of the calorimeter and contents can be measured over small temperature intervals, thus approximating the heat capacity at a definite temperature; troublesome corrections, due to the evaporation of the calorimetric liquid and to the energy supplied by the stirring device, are eliminated.

A series of check experiments on the specific heat of water shows the order of reproducibility of results which can be obtained with this calorimeter to be 1 part in 2,000. Measurements made at temperatures between 0 deg. and 40 deg. cent, gave results which agree to within the limits of experimental accuracy with the unpublished results of a long series of experiments made in the usual form of stirred water calorimeter. The results are also in satisfactory agreement with the most probable values deducible from the data of the most careful investigations published by other observers.

The original article gives the details of design and a diagram of circuits used, as well as tables of calibration of thermometers by the calorimeter. (27 pp., 11 figs.)

THE SPECIFIC HEAT AND HEAT OF FUSION OF ICE, H. C. Dickinson and N. S. Osborne.

The paper describes one of a series of investigations undertaken, at the request of the refrigeration industries, by the Bureau of Standards, at Washington, D. C., for the determination of constants which are of fundamental importance in the design and operation of refrigerating machinery. It refers particularly to the specific heat and heat of fusion of ice. A previous determination of the heat of fusion of ice made at the Bureau of Standards was published in 1913, at the time of the meeting of the Third International Congress of Refrigeration in Chicago. At that time, it was stated that the results presented were subject to a slight uncertainty on account of the lack of adequate knowledge of the specific heat of ice near the melting point. This has been the subject of the work described in the present article.

After a brief reference to previous work and a description of the calorimetric method employed (the aneroid calorimeter described in the preceding abstract was used), the authors proceed to the description of the material and the preparation of the samples, a matter of great importance in view of the fact that even small amounts of impurities are liable to cause a considerable increase in the apparent heat capacity due to incipient melting of portions of the ice. The experimental procedure used and methods of calculation are described in some detail and the experimental results, giving the specific heat of ice, are presented in several tables and diagrams, the tables expressing the observed mean specific heats of the several samples with reference to the initial and final temperatures θ_1 and θ_2 of the respective experiments ($S_m = \frac{H_2 - H_1}{\theta_2 - \theta_1}$ where $H_2 - H_1$ represents the total heat per gram over the interval $\theta_2 - \theta_1$).

A preliminary plotting of the observed mean specific heats indicated that the curves of specific heat were asymptotic to a straight line, the departure from which was apparent on the above temperatures varying from -8 to -2 deg. for various samples, which appears to corroborate the observation of Smith, that the specific heat of ice tends toward constancy as the impurities in the ice are reduced. As regards

the relation between apparent specific heat of ice and dissolved impurities, it has been assumed that the measure of the departure of the specific heat of a specimen of ice from a linear function of the temperature depends upon the degree of purity. While the results upon four samples of ice, all of high and yet different degrees of purity, agree with this assumption, it does not necessarily follow that the assumption is substantially correct and it is quite possible that the relation of the specific heat of pure ice to the temperature is other than linear, perhaps rapidly increasing near zero.

It has been found that at a given temperature, θ , between -40 and -2 deg. for the purest ice experimented on the specific heat, in 20 calories per gram per degree is represented within the limits of experimental accuracy by the equation

$$S = 0.5057 + 0.001863 \theta$$

and that from -2 to $-.05$ deg., the specific heat for pure ice does not depart from the value given by the above equation by more than

$$\frac{0.004}{\theta^2}$$

The specific heat of impure ice at a temperature θ above -40 deg. is greater than that of pure ice by lL/θ^2 , where L is the heat of fusion, and l the initial freezing point.

The value found for the heat of fusion of ice is 79.76, 20 deg. calories per gram, which is within $\frac{1}{4000}$ of the value previously determined at the Bureau by the different method, employing a stirred water calorimeter.

The original article gives the table of total heat of ice and water at temperatures for ice from -20 to $+32$ deg. Fahr. and for water from $+32$ to 100 deg. Fahr. (29 pp., 7 figs. e).

CLEVELAND ENGINEERING SOCIETY

Journal, vol. 7, no. 4, January 1915, Cleveland, O.

An Example of Novel Shore Construction and General Talk on Jetty Action, Walter P. Rice
The Useful Recovery of Heat Losses in Internal Combustion Engines, J. B. Merriam (abstracted)
Founding as an Art and Adjunct to Engineering, Thomas D. West

THE USEFUL RECOVERY OF HEAT LOSSES IN INTERNAL COMBUSTION ENGINES, J. B. Merriam.

The paper describes a new method of recovering heat losses in internal combustion engines, and also discusses the causes of certain limitations in water cooling in the present engines.

It is a well-known fact that, with an ordinary water supply, an engine will work satisfactorily when the temperature of water is around 150 deg. Fahr., but if the temperature of the water in the jacket is allowed to rise, the cylinder will burn or score even before the jacket water reaches, say, 250 deg. The elements which affect the flow of heat from the inside surface of the combustion chamber to and into the water are:

First. The difference in absolute temperature or the relation of the two temperatures to the absolute zero point. This is measurable, but not sufficient to cause a disastrous interference to the flow of heat which takes place somewhere between the surface of the combustion chamber and the water.

Second. The amount of surface exposed: in an engine al-

ready built it is constant, that is, it does not change with the change of water jacket temperature from 150 deg. to 250 deg., and therefore cannot affect the results when such a change takes place.

Third. The time of exposure: after the revolutions of the engine have been determined, it also becomes constant.

Fourth. The unit of resistance to the flow of heat: this appears to be the only element subject to change when the jacket water temperature materially rises.

To find out why it changes, the author refers to the familiar experiment of heating water in a rough cast iron vessel. It is there found that no visible change occurs below 140 deg. Fahr., but above it, small bubbles are formed which adhere to the surface of the iron. These bubbles increase both in number and size with rise of temperature, and by the time the water has reached 200 deg., the inside surface of the vessel seems fully covered with bubbles.

The secret of the entire difficulty of running an engine

FIG. 9 THE MERRIAM SYSTEM OF RECOVERY OF HEAT LOSSES IN INTERNAL COMBUSTION ENGINES

with the water jacket temperature above 150 deg. lies in this formation of bubbles, since, if any portion of the surface continues to increase in temperature after the formation of the bubbles, spheroidal action takes place and thus constitutes a critical interference to the flow of heat, or, which is equivalent to it, to the cooling effect of the water.

It has been further observed that each of these bubbles increases in size and finally breaks away, and a new bubble rapidly forms on the same spot, which is somewhat hotter than the metal surrounding it, because it has been protected from contact with water by the previous bubble. If, however, the water is disturbed in the vessel so as to put it in motion, the bubbles break off while much smaller, the size of the bubbles decreasing as the velocity of the water is made to increase. Through these facts, the author comes to the conclusion that the formation of these bubbles and their adherence to the cylinder walls could best be prevented by very high velocities of the jacket water, which would permit both the using of higher temperatures of water and producing as a by-product a considerable amount of steam which can be employed for various purposes.

A series of experiments were made on a 150 h.p., 4-cylinder, 12 $\frac{1}{4}$ x 14 in. Bruce-McClellan type engine, fully equipped

with thermometers, flow meters and gages, and a centrifugal pump which was used to force the water at high velocity through the cylinder jackets. The velocity of the water was maintained at from five to ten times that ordinarily used. The measurement was substantially as shown in Fig. 9. With this engine, it was found that it required less than 30 minutes to bring the system up to 10 lb. steam pressure, while in the other tests, the pressures have been increased to 50 lb., which is equivalent to a temperature of 297 deg. If an enclosed cooling system be used, as shown in the above figure, and only steam allowed to escape, then all of the water used must eventually be turned into steam and the entire amount of heat of the fuel, usually referred to as lost to the jacket water, will be fully recovered in the heat units restored in the steam. This appears to be actually the case. With a well designed exhaust-gas boiler, one-half of the 35 per cent of the total heat units of the fuel lost to the exhaust can be recovered and added to the 35 per cent recovered from the water jacket, which will give approximately 50 per cent of the total heat units of the fuel available in the form of low pressure steam. An exhaust boiler, or any low pressure or heating boiler, can be included as a part of the system.

At the same time, the efficiency of the engine as shown by

TABLE 4 RESULTS OF TESTS OF GAS ENGINE WITH WATER COOLING AT HIGH SPEED IN THE JACKET

	$\frac{1}{4}$ Load	$\frac{1}{2}$ Load	$\frac{3}{4}$ Load	Full Load
Brake h.p.	43	77	112	151
	11-38	12-08	10-30	9-58
Gas h.p. per hour	14.3	11.4	9.75	9.28
Temperatures, deg. Fahr.:				
Water supply.....	52	52	52	52
Inlet to cylinder	253	253	253	253
Outlet cylinder.	260	262	266	267
Exhaust manifold	256	257.5	260	260
Steam pressure, lb....	17.5	17.75	18	18
Lb. of water evaporated per h.p. hour	7.3	5	4.3	3.7

Table 4, is also improved by this process, due to the higher temperature of the cylinders. The small figures show the gas consumption of the same engine when running with the cylinders at ordinary temperature. No difficulties or detrimental effects have been experienced when operating an engine under this process at maximum load and with the water jackets under full steam pressure and temperature. On the contrary, the resultant condition is favorable, since the water passes through the cylinder at such high velocity that the difference between the temperature of entering and outgoing water is less than 15 deg. and the cylinder and all parts of the engine are maintained at a uniform temperature. This temperature also remains constant irrespective of the load, as it is determined entirely by the steam pressure carried on the system. Another advantage claimed for this system is that the thermal efficiency of the engine is improved so that the fuel consumed is at least two per cent less at maximum load and fully 15 per cent less at one-quarter load as shown by tests.

A brief list of references on matters connected with the subject of the paper is appended to the original article (13 pp., 4 figs. *deA*).

AIR CONDITIONING, J. Irvine Lyle

The paper discusses present methods of air conditioning and then describes a number of applications of air conditioning installations. Its interest is in showing the wide field of application for this kind of apparatus and the valuable results which may be obtained with it.

The Lord & Taylor department store building, at Thirty-ninth Street and Fifth Avenue, New York City, is a good example of the application of air conditioning to a department store. With 82 deg. outside, inside the temperature was only 73 deg. and it felt cool and invigorating to a person coming in from the street.

There are many industrial plants in addition to textile mills where the question of humidity is of greatest importance. Four years ago there was not a bakery in the United States that was equipped for air conditioning. Today there are thirty odd bakeries having control of humidity in their dough-rooms, so as to regulate the germination of the yeast and prevent the gases generated in the raising process from being given off. On a commercial basis, figured on the continuous operation of a bakery, it gives about fifteen more loaves of bread per barrel of flour and makes whiter, better bread. The same applies to candies. Hard candies require low temperatures and low humidities for proper drying. For chocolates, low temperature must be provided in order to congeal it.

Control of humidity conditions is still more important in the case of macaroni. If dried too quickly, it will break all to pieces when the housewife gets it, and if dried too slowly, it is liable to mold. In printing establishments handling multicolor or lithographic work, the control of the humidity is absolutely necessary if they are going to turn out high grade work and do so continuously. In some cases as much as two months elapse between the time the first color is put on the paper and the last color is applied, and unless the temperatures and humidity conditions are maintained constantly uniform, it is difficult to obtain uniform results from the color plates.

From a hygienic point of view, air conditioning may also be very valuable.

In the stemming rooms of tobacco plants dust is so thick that the girls generally have to work with sponges or handkerchiefs over their noses. The machines are so constructed that it is practically impossible to remove all the dust, but such elimination as is accomplished is done by furnishing humidified air to the room. In a plant making cotton or straw mattresses, air conditions were so bad that they never had a man who was able to work two months in winter without losing a few days each month. The health department made them put in an air conditioning plant and now the men work continuously and there is no loss of time by the men.

Among other things, the author exhibited jars containing a week's dirt from the air in a public school in Brooklyn, showing the great need of air purification in such establishments (34 pp., 28 figs. *d*).

FRANKLIN INSTITUTE

Journal, vol. 179, no. 3, March 1915, Philadelphia.

Paints to Prevent Electrolysis in Concrete Structures,
Henry A. Gardner (abstracted).

PAINTS TO PREVENT ELECTROLYSIS IN CONCRETE STRUCTURES.
Henry A. Gardner

The paper describes a series of tests made to determine what type of coating is best suited for the protection of metal imbedded in concrete against the action of electrolysis.

The paper fully describes the method of testing. The rods, previous to bedding, were thoroughly cleaned from scale and rust, then two coats of paint were applied, allowing a week's time for drying between the coats. Cement mortar was prepared from one part of Portland cement and two parts sand. In making up the specimens for tests, the author considered the objection to using paints which dried upon the metal to a glossed surface, thus preventing a proper bonding of the cement. To overcome this difficulty, he applied to the painted surface while it was still tacky (not dried), sharp particles of sand or similar material which, when allowed to drain upon a painted surface, became attached to the paint and dried with it, forming a rough surface resembling coarse sand paper. Emery powder abrasives and other substances were tested, but fine clean white sand was found to be the most useful.

In the test specimens where cracking has occurred the anodes showed considerable rust, the paint coating originally applied having been destroyed. On the cathodes in series 1 (painted iron rods, $\frac{1}{2}$ in. in diameter and 12 in. in length, embedded in concrete cylinders, in upright position in mold, about an inch apart, and one inch from the bottom of the mold) the paint coatings were still intact, although some had apparently been affected by the moisture and the hydrated lime in the wet concrete, chalky surfaces being shown. Wherever there were small voids in the concrete, at or around the painted anodes, corrosion was most severe, and at such places pitting was evident.

The protective coating around the anode and cathode parts imbedded in the concrete cylinders which did not crack and which carried only a slight current, were found to be in a very good state of preservation. The breaking down of a film around the imbedded iron rods was always recorded by a sharp rise in amperage as well as by a fizzing sound, due to the increased evolution of hydrogen gas developed by the electrolysis of water in the damp concrete. This gas generally carried some water with it, forming small bubbles which burst with an audible explosion when a lighted match was placed in contact with them. The hydrogen gas seemed also to have a reducing or softening action upon some of the oxide bodies and carried to the surface of the cylinder considerable quantities of soft oily products which deposited around the anode and later hardened in contact with the air. Iron oxide was also carried to the top surfaces on some of the specimens by the action of the gas and water and was there deposited as a dark brown stain.

There can be no doubt that the nature of the paint films has considerable bearing upon the action of the hydrogen gas which was found to develop during the tests. Some paints gave good bonding tests but failed to act as insulators. Two lacquers composed of collodion and gutta-percha, res-

spectively, dried to a flat surface, and gave a much better bonding than paints of a similar composition when dried to a glossed surface. Good bonding tests shown by several of the water paints are explainable through the wet concrete exercising a solvent action upon such paints, which gives opportunity for direct contact with the steel. Some paints which gave excellent results in the insulating tests gave conversely poor results in the bonding tests. Among these may be mentioned two paints composed of sandarac and shellac. Most of the oil pigment paints made with raw linseed oil gave poor or only fair results. It is probable that the raw linseed oil fails to dry hard, and although apparently well dried, remains in a semi-oxide condition so that the oil film is rather porous and therefore inefficient as insulation. Much better results were obtained with boiled linseed oil, a product which dries to a harder, less porous and more fully saturated film.

It is quite likely that the nature of the pigment used in a paint designed to prevent electrolysis of imbedded metal will have some bearing upon the results obtained from its use. Theoretically, pigments which are of a nonconducting nature should be preferable, such as inert pigments like asbestos, china clay and silica. There should also be present in a paint a sufficient quantity of rust-inhibitive pigment, (basic pigments or pigments of the chromate type), to produce a passive condition in the steel. The best results were given by protective compounds composed of processed and heat treated tung oil (Chinese wood oil) which dried to a hard nonporous film of a saturated nature. The author also recommends that the painted metal be "sanded" if possible.

The results of tests are reported in several tables. (24 pp., 14 figs. *et*.)

INSTITUTION OF PETROLEUM TECHNOLOGISTS

Journal, vol. 1, part 2, December 1914, London

Initial Equipment and Organization as affecting the ultimate success of Oil Development Companies, John Wells.
Oils from Peat, Dr. F. Mollwo Perkin (abstracted).

OILS FROM PEAT, Dr. F. Mollwo Perkin

The paper discusses the production of oils from peat and covers the chemistry of peat oil technology, work already done and commercial possibilities.

According to the statement of the author, there are many difficulties in the way of profitably extracting oil and other by-products from peat, but he does not believe that these difficulties are insurmountable. The initial difficulty and the one as a result of which most peat propositions have turned out failures, is to remove the large amount of water invariably held by the peat.

Here the question of economy of fuel must be taken into account. When peat is briquetted and dried so as to contain from 18 to 20 per cent of water, then on being charred, each ton produces from 5000 to 6000 cu. ft. of gas, having an average calorific value of 130 B.t.u. The process once started, the gas produced by carbonization is more than sufficient to continue the process and there is a certain amount of residual gas which can be employed for other purposes. But when the amount of moisture exceeds 20 per cent, the quantity of gas produced is not sufficient to carbonize completely the peat and extra fuel has to be employed.

On the plant of the Tarless Fuel Company, which is worked

under a considerable vacuum, peat may be carbonized satisfactorily and the by-products collected with a lower fuel consumption than when the distillation is carried out at atmospheric pressure.

How the water is to be eliminated in the first place is still an open problem. If the fibres are broken or disrupted, a much larger proportion of water can be forced out than from freshly dug peat, and a comparatively dry cake containing say from 30 to 35 per cent of moisture can be obtained. The peat can also be ground after it has been dug, without previous drying, the object of grinding being to break up the cells. Then the peat is briquetted and dried either by atmospheric exposure or by warm air. The author's experience is that peat briquettes should first be partially air dried before artificial heating is employed. Electrical processes have also been suggested for disintegrating the fibre. The labor item is a very serious element in all plans of making oil or carbon from peat.

The article contains a cost estimate for an experimental plant to produce 5 tons of dried peat per day for six months. (14 pp. *gp*).

SCIENTIFIC SOCIETY OF THE ROYAL TECHNICAL COLLEGE, GLASGOW

CALCULATION OF CENTRIFUGAL STRESSES IN TURBINE ROTORS, Wm. KETT

The paper discusses the calculation of centrifugal stresses in rotors, solid shaft, hollow shaft or drum type. As the original publication of the Society before which it was presented is not available, the abstract is made from a reprint of the paper in the *Mechanical Engineer*, vol. 35, No. 897, April 2, 1915, and April 9, 1915, page 257.

In a rotating body, two principal stresses have to be considered—the tangential or hoop stress f_t and the radial stress f_r (fig. 10). An elementary portion of the body being considered, the stresses acting on the surfaces of it must be in equilibrium with the centrifugal force of the element, this condition providing a relation between the stress and the velocity, while the consideration of strains gives other relations. These are written down in the terms of the radial displacement of the material at any radius, the value of this displacement being referred to as *expansion* and denoted by the symbol u . From the consideration of velocity and strains, a differential equation is obtained, which, when integrated, gives a general expression for u , containing two constants to be determined by the boundary conditions which exist in each particular case.

The equations will always be found to divide themselves into two parts; one deals with the effect due to the mass of the rotor body alone and the other with the effects of the external loads which it carries, such as the blading. This is of considerable value as it enables the designer to recognize whether excessive stresses are due to loading or form. The following notation and constants are used by the author: specific weight of steel = .283 lb. per cu. in.; Young's modulus for steel = 30×10^6 lb. per sq. in.; Poisson's ratio for steel = 0.3; radial stress = f_r ; tangential stress = f_t ; expansion = u ; external radius = R ; ratio $\frac{R_o}{R} = a$; internal radius = R_o ; ratio $\frac{r}{R} = b$; any radius = r ; speed in r.p.m. = N ; radial stress on external surface = φ ; total

centrifugal force of rim and blades = Q ; area of section of rim or drum = A .

Solid Shaft Rotor. The rotor body is composed of a solid shaft and the blading is fitted into grooves cut in the periphery. This means that a series of rings is formed on the surface of the shaft and in order to carry out the calculation, some assumption is necessary: either that the true radius of the shaft is the mean radius of the grooves, or the radius may be taken as that of the bottom of the grooves, in which case the collars are considered as an addition to the blade loading. The second method is perhaps the safer, as it leads to higher stress values. In the theory, consideration has to be given to a third principal stress; that is, the axial stress. Its equation is not given as it is of no practical importance,

FIG. 10 CENTRIFUGAL STRESSES IN TURBINE ROTORS

but its influence on the radial and tangential stresses is considered in the determination of the expressions given for these. The general equations are:

For the radial stress at any radius r :

$$f_r = 3.46 \frac{N^2 R^2}{10^6} (1 - b^2) + \varphi.$$

For the tangential stress at any radius r :

$$f_t = 3.46 \frac{N^2 R^2}{10^6} (1 - \frac{2}{3} b^2) + \varphi.$$

Obviously, the maximum stresses are reached when $b = 0$ (that is, at the center of the shaft) and for these conditions, the radial and tangential stresses are equal, giving

$$f_r(\text{max}) = f_t(\text{max}) = 3.46 \frac{N^2 R^2}{10^6} + \varphi.$$

The article discusses an example of this type of rotor and gives in graphical terms the results of complete investigation of the stresses occurring in it.

Hollow Shaft Rotor. The difference between this type and the solid shaft rotor is that the inner core of the shaft is removed, either for the purpose of cutting down the weight or to insure the soundness of the material subjected to the highest stresses. In the formulae following, the symbol a represents the ratio of the inner radius to the outer radius, while b has the same meaning as before. The general relations in this case are

$$\text{Radial stress} = f_r = 3.46 \frac{N^2 R^2}{10^6} \left\{ 1 - b^2 + a^2 \left(1 - \frac{1}{b^2} \right) \right\} + \varphi \left\{ \frac{b^2 - a^2}{b^2(1 - a^2)} \right\}$$

$$\text{Tangential stress} = f_t = 3.4 \frac{N^2 R^2}{10^6} \left\{ 1 - \frac{2}{3} b^2 + a^2 \left(1 + \frac{1}{b^2} \right) \right\} + \varphi \left\{ \frac{b^2 + a^2}{b^2(1 - a^2)} \right\}$$

In the equation of radial stress, the maximum value of the first term occurs at a value of b different from that at which the second term reaches its highest value. Consequently, no exact expression of a simple nature can be given for the maximum radial stress. Since, however, the second term is usually of much less importance, the equation for the maximum might be made to suit the condition for the first term.

SOCIETY OF AUTOMOBILE ENGINEERS

THE HIGH-SPEED, HIGH EFFICIENCY EIGHT CYLINDER
V-TYPE ENGINE, D. McCall White

The paper, after discussing in a general manner the eight-cylinder V-type automobile engine, compares it with either the four or six cylinder engines. In the matter of size, the eight (the author refers to the Cadillac Eight) is enclosed in practically the same hood space as was the four cylinder engine. The length is no greater but there is about a two-inch greater width. The weight is 50 to 60 lb. less than that of the previous four cylinder engine. From a mechanical standpoint, the V-type eight has the advantage of permitting the use of a short sturdy crankshaft, having only four throws.

As regards cooling, each block of cylinders is treated as a separate unit, although one radiator is common to both. There are, therefore, all the advantages of the four cylinder construction without its disadvantages. Beside, in the V-type eight, the amount of space to be cooled in each cylinder block is so small relatively that the variations in the temperatures of the forward and rear cylinders need scarcely to be taken into account. The temperature of cooling water is controlled by a thermostatic arrangement similar to that in an aneroid barometer. Forced lubrication is used, an oil pump of the gear type driven at one-half engine speed, being situated at the lowest point on the front cover of the engine, which makes it very accessible for examination. The wrist pins, cylinder walls and camshaft rockers are lubricated by the residue oil which is constantly coming out from the end of the bearings. As regards durability, the author believes that a well designed and properly made eight will considerably outlast an equally well designed and made six. His reason for this statement is that vibration more than use shortens the life of a motor: in the V-type eight, properly designed and manufactured, vibration is reduced to an almost negligible factor, and hence to the same extent longevity is increased. (20 pp., 1 fig., to be continued. *d*).

HIGH SPEED STEELS, Fred. C. A. H. Lantsherry

The paper discusses the subject of high speed steels and presents a very clear and interesting historical and general review of the subject.

Among other things, the author describes an investigation made by him at the works of the Birmingham Small Arms Company with a view to determining the most suitable steel for the manufacture of milled twist drills. The properties required for a twist drill are more exacting than those required in a turning tool, in addition to which, in the turning tool the principal factor is undoubtedly hardness while in a drill mechanical strength and toughness are at least of equal, if not of greater importance. It appeared, therefore, necessary to test steels in a way adapted to this particular purpose.

Consequently, a special drilling machine was designed for the test, making it possible to obtain feeds of from 0.010 to 0.0675 in. per revolution and speeds of from 100 to 400 r.p.m. A standard drill size of $\frac{15}{16}$ in. diameter was adopted for the test, as being a size which is very largely used in English machine shop practice. A standard speed of 400 r.p.m. and a feed of 0.019 in. per revolution were adopted for the test in which the drills were lubricated, but in order to give some idea of the red-hardness of the various steels, tests were made in which the drills were run dry. For these tests, the same feed was maintained but the speed was reduced to 305 r.p.m. The number of inches of steel drilled was then taken as a measure of the suitability of that particular high speed steel for the purpose of drill making. In every case the drill was run until it absolutely refused to cut any more steel, when the point of the drill was quite worn away or the drill had broken.

A large number of proprietary steels were tested in this way but none of them were found to be particularly suitable for drill making. Special experiments were therefore made on the influence of tungsten, chromium and vanadium and the drilling properties of high speed steels, with carbon content as nearly as possible at 0.6 per cent. The first series of steels contained also constant chromium content, while the tungsten was increased from 10 per cent to 25 per cent. It was found that the efficiency of the steels as drills increased to a maximum and then fell as the tungsten passed 14 per cent. This figure was taken as the most desirable tungsten content, and upon this basis, another series of steels was obtained in which the chromium was increased from 1.5 to 7.5 per cent, the efficiency of the steel reaching a maximum and then falling off again as the chromium increased. It was found that the effect of molybdenum was slight and not sufficiently promising to warrant its use.

Altogether it was found that a really excellent high-speed steel is that containing 14 per cent tungsten and 4 per cent chromium, although the author does not claim that this is the best combination possible. Drills of the composition finally arrived at were deemed poor if they failed to penetrate 100 in. of the test steel. Further, the new steel would cut at a penetration of 25 in. per minute, while the ordinary steel would not cut at a greater penetration than 12 in. per minute.

In the discussion which followed, in answer to a question as to whether an addition of say 1 per cent of vanadium above the quantity eliminated in manufacture would be of any use, the author told of tests of a special steel containing 1 per cent of vanadium; drills made from it were of absolutely no use. It appears, therefore, that the only valuable effect of vanadium is that which it has during the process of making the steel. (24 pp., 8 figs. *hgc*).

MEETINGS

CHICAGO, MARCH 19

A meeting of unusual interest was held by the Chicago local section on March 19, devoted to the subject of Refrigeration with special reference to Ice-Making as a By-Product of Central Stations. The meeting which was held in the ball room of the Hotel La Salle, was addressed by Heywood Cochrane, western manager of the Carbondale Machine Company, Chicago, who outlined the principal refrigerating methods in which ammonia is used as the refrigerant, then discussed the economies of usual ice-making practices with reference to the supplies of power, distilled water and steam, and finally explained the advantages of suitable combinations of such plants with power plants having excess exhaust steam available, with which important savings can be effected. Mr. Cochrane referred particularly to absorption machines and discussed a number of forms of installations of such apparatus in connection with steam plants, showing results and test data. He stated that in the case of a lighting plant with low revenue from the sale of current, the installation of a properly designed refrigerating auxiliary will prove more profitable than the original lighting plant, and in the case of a combined water and lighting plant, the addition of refrigerating equipment is even more advantageous. Mr. Cochrane's paper drew out a large amount of discussion, interesting addresses being presented by Otto Lahr and John M. Westerlin, both consulting refrigerating engineers of Chicago and by Fred Wittenmeier, vice-president and chief engineer of Kroeschell Bros. Ice Machine Co. of Chicago. A more complete account of the meeting will appear in an early issue of *The Journal*.

BUFFALO, MARCH 25

At a meeting of the Buffalo Engineering Society on March 25, an address on Our Navy and What it Means was delivered by Edward Breck, Field Secretary of the Navy League of Washington, D. C. Dr. Breck illustrated his address with a number of stereopticon slides, showing the progress of the American Navy up to the present time. He presented in addition some very interesting statistics regarding the growth of the navies of the world, as well as historical data which proved conclusively that preparedness is the best and only way to avoid war.

About 200 members were present at the meeting.

BOSTON, MARCH 31

At a local meeting in Boston on March 31, Harry Gay, equipment engineer in charge of the work for Stone & Webster Engineering Corporation, gave an illustrated talk on the Engineering Equipment of the New Technology Buildings; Geo. E. Libbey, of the firm of Hollis French & Allen Hubbard, presented the Heating, Ventilating and Sanitary Features of the Work; and A. L. Williston, President of Wentworth Institute, gave an illustrated talk on the Lay-out of Educational Institutions.

ST. LOUIS, APRIL 7

At a joint meeting of the St. Louis Engineering Societies on April 7, Edward E. Wall gave an extremely interesting paper on the City Water Supply. He spoke first

of the steps necessary to bring to the highest efficiency the present water supply, which averages 120,000,000 gallons a day, with a maximum capacity of double that amount. The speaker advocated a new covered storage basin at Baden, additional pumps and pipe line, and the rebuilding, enlarging and covering of the Compton Heights Reservoir.

The requirements of ten years from now were next discussed. At that time, it is believed, the city's water requirements will be double the present amount. This increased supply can be obtained either from the Mississippi River by substantially duplicating the present plant, or from the Missouri River. The estimated cost of the two schemes is about the same, and since the Missouri supply presented a number of advantages, the author favored working along this line.

BUFFALO, APRIL 8

On April 8, the Buffalo Engineering Society accepted the invitation extended by the Federal Telephone and Telegraph Company and inspected the new automatic telephone system installed in their Buffalo plant. Mr. Hershey of Chicago presented a detailed explanation of the construction and operation of the automatic telephone apparatus and illustrated his talk with stereopticon slides. After the lecture a thorough inspection trip was made through the plant and the apparatus was shown and explained under operating conditions.

PHILADELPHIA, APRIL 12

A joint meeting with the Philadelphia Section of The American Institute of Electrical Engineers was held on April 12. J. S. Barstow read a paper on Turbine Driven vs. Engine Driven Units in Small Capacities. Mr. Barstow showed a number of slides illustrating the various apparatus mentioned. The paper was followed by a general discussion.

NEW YORK, APRIL 13

The monthly meeting of the Society in New York for April was devoted to the subject of elevators, with particular reference to the traction type of elevator machine used in the tall buildings. On account of the importance of this question in New York City, the paper attracted an unusually large audience, approximately 480 being in attendance. The meeting was addressed by David Linquist, chief engineer of Otis Elevator Company of New York, the subject of his paper being: Modern Electric Elevator and Elevator Problems. He took up first, the traction electric elevator, giving comparisons of the gearless traction type with the geared traction type, second, installations with details of their performance in service, efficiency, power consumption, acceleration and retardation, and third, the application of ball and roller bearings to elevator machinery. The address was profusely illustrated by lantern slides and drew out considerable discussion. A more complete account of the meeting will appear in an early issue of *The Journal*.

SAN FRANCISCO, APRIL 16

The San Francisco Section of The American Society of Mechanical Engineers held its spring meeting on April 16. The paper of the evening was read by G. C. Noble on the

Design and Test of a Large Reclamation Pumping Plant. The plant in question is that built for Reclamation District No. 1500, otherwise known as the Sutter Basin project, situated in the Sacramento valley near the confluence of the Sacramento and Feather rivers. This plant is probably the largest centrifugal pumping plant in the United States if not in the world, having a total capacity of 676,000,000 gal. of water per day, and requiring 5000 h.p. for its operation. Six 50-in. diameter pumps, operating against a maximum head of 29 ft. at a speed of 248 r.p.m., are direct-connected by means of flexible leather link couplings to constant speed motors. Duplex motor-driven vacuum pumps are employed for priming purposes and the plant equipment includes in addition the usual accessories. Mr. Noble's paper was illustrated by lantern slides. The entire subject is one of peculiar interest to Pacific Coast engineers.

NECROLOGY

JACOB ROBINSON ANDREWS

Jacob Robinson Andrews was born September 6, 1861, at Bridgewater, Mass., and was educated at Bridgewater High School and Bridgewater Academy. In 1879, he obtained employment as apprentice in the machine shop of the Hyde Foundry at Bath, Me. He was rapidly advanced to the position of foreman, and a few years later was made vice-president and general manager of the Hyde Windlass Company. When this firm separated from the United States Shipbuilding Company in 1905, he became president.

Mr. Andrews worked untiringly to advance the interests of American shipping and was one of the best known figures in shipping circles. He was a member of the Society of Naval Architects and Marine Engineers and the Engineers Club of New York. He died in New York City on March 25, 1915.

JAMES FINNEY McELROY

James Finney McElroy was born in Greenfield, Ohio, on November 25, 1852. He attended the Salem Academy at South Salem, Ohio, in 1869 and the Bloomingburg Academy at Bloomingburg, Ohio, from 1870-1872. He was graduated from Dartmouth College in 1876 with the degree of A.B. and received the degree of A.M. from there in 1879. From 1876-1880, Mr. McElroy was principal teacher of the Indiana Institute for the Blind at Indianapolis and from 1880-1887 he was superintendent of the Michigan Institution for the Blind, at Lansing, Mich. For this institution, he designed and constructed the heating and power plant.

In 1887, he organized the McElroy Car Heating Company at Buffalo which operated under its own patents. In 1889, this concern was combined with the Sewell Car Heating Company forming the Consolidated Car Heating Company in Albany of which Mr. McElroy was consulting engineer and acting president to the time of his death. He died on February 10, 1915.

WILLIAM McINTOSH

William McIntosh was born August 20, 1849, and had a common school education. From 1867 to 1870 he served an apprenticeship with the Chicago, Milwaukee and St. Paul Railway. He was employed by the Chicago and North

Western Railway for 27 years, in the capacity of foreman at Waseca, Minn., and Huron, S. Dak., and of master mechanic at Winona, Minn. He left this position to become superintendent of motive power with the Central Railroad of New Jersey. When in 1909 he resigned on account of ill health, he claimed forty years of active railroad service. He died on March 16, 1915.

Mr. McIntosh was a member of the New York Railroad Club, the Canadian Society and the Engineers Club.

PERSONALS

Arthur W. de Revere has been appointed district sales manager of The Terry Steam Turbine Company, with offices in Chicago, Ill.

Daniel M. Luehrs has severed his connection with the American Blower Company, Detroit, Mich., as engineer in charge of the air washer department, and is now general superintendent of the Guilford Avenue Plant of the Crown Cork and Seal Company of Baltimore, Md.

M. C. Stuari, formerly assistant steam engineer at the Cambria Steel Company, Johnstown, Pa., has been appointed a mechanical engineer at the U. S. Naval Engineering Experiment Station, Annapolis, Md.

Claude A. Bulkeley has accepted the position of chief consulting engineer with the Canadian Domestic Engineering Company, Ltd., Montreal, Que., Canada. Until recently Mr. Bulkeley practiced consulting mechanical and electrical engineering in New York City.

Walter N. Cargill has been appointed superintendent of power and lines for the Rhode Island Company, Providence, R. I. He was until recently associated with the Stone & Webster Engineering Corporation of Boston.

Thomas H. Belcher has resigned his position with the Black-Clawson Company, Hamilton, O., and has accepted the position of manager of the Carthage Machine Works, Carthage, N. Y.

Homer S. Burns has accepted a position with the Freeport Sulphur Company, Freeport, Tex., as mechanical engineer. He was until recently in the employ of Westinghouse, Church, Kerr & Company, New York, as superintendent.

Clarence Boyle, Jr., formerly district sales manager of the Taylor-Wharton Iron and Steel Company, Scranton, Pa., has become associated with Clarence Boyle, Inc., Chicago, Ill.

Reginald J. S. Pigott is severing his connection with the Interborough Rapid Transit Company, New York, as mechanical construction engineer, to take up the position of power engineer for the Remington Arms-Union Metallic Cartridge Company at Bridgeport, Conn.

STUDENT BRANCHES

Members of student branches are requested to notify the Secretary of any change in address as promptly as possible, in order to facilitate delivery of The Journal.

ARMOUR INSTITUTE OF TECHNOLOGY

At a meeting of the Student Branch of Armour Institute of Technology on April 8, F. G. Gasche, chief mechanical engineer of the Illinois Steel Company, gave an illustrated talk on The Evolution of the Modern Steam Engine and Power Plant Transmission as Developed in the Steel Industry. Mr. Gasche told of the rapid development of the steam engine for blower purposes and showed how fast the D-slide valve and the Zeuner diagram were going out of use. The methods used in making I-beams, channels and steel rails were clearly demonstrated by the pictures shown.

CARNEGIE INSTITUTE OF TECHNOLOGY

The regular meeting of the Carnegie Institute of Technology Student Branch was held on March 10. Mr. Chester of Babcock & Wilcox Boiler Company read a paper on Modern Boiler Practice. He spoke first about the new A.S.M.E. Boiler Code, and told of many of the variations in boiler practice which it was designed to eliminate. In discussing boiler plants, he said that the large unit was desirable, but that it was usually broken up into a number of smaller units so that one or more could be held in reserve. Much progress is being made in combined boilers, superheaters, and economizers. Superheaters first became common in the United States in 1900, and at present about one fourth of the total boilers are equipped with them. Stacks are being replaced by mechanical draft, and more attention is being paid to the brickwork, so as to stop leaks, etc.; higher temperatures can be obtained than the fire brick will stand, and it has been found difficult to hold up the arches. By means of slides Mr. Chester illustrated many of the different types of boilers, settings, and stokers.

The meeting of the Branch, held on April 14, was one long to be remembered by the members, inasmuch as they were addressed by Dr. John A. Brashear, President of the American Society of Mechanical Engineers.

Professor W. Trinks first spoke to the graduate members briefly, explaining to them the advantages to be derived by becoming members of the A.S.M.E., and urging them to join the organization.

Dr. Brashear was then introduced and gave an interesting talk on Engineering as Applied to the Construction of Telescopes. He said, we need the civil engineer for location, the mechanical engineer for construction, the electrical engineer for control, and so on down the list of the various branches of engineering. His talk was illustrated by lantern slides. With the aid of these, he described astronomical instruments from their early crude forms to their present highly developed forms and showed the famous collection of Chinese instruments on the walls of Peking, many of which had been taken by the various nations concerned in the Boxer Rebellion. He stated that every nation but Germany had returned these, and that he expected Germany to do likewise. For more than four thousand years the Chinese kept records upon which astronomers have placed great dependence. He showed and described many different types of telescopes, among them being those of Lord Ross and Sir Howard Grubb, the great forty-eight inch of Herschel, the twenty-six inch reflector at Lick Observatory, and the Snow Telescope at the same place.

Dr. Brashear dwelt for some time on the mechanical and electrical details of the telescope. It is no longer a difficult task to make observations with a large telescope. The observer merely sits in a chair and by simply touching buttons or moving levers, he can make these great masses take any position, hairline adjustments being easily made. If the telescope rises above the observer's eyes he can raise the floor to any desired level.

He showed the telescopic photographic apparatus, which he said had done so much for astronomy. The retina of the eye becomes tired very quickly, and hence visual observations are limited. The photographic plate, however, can be exposed to the action of heavenly bodies for many hours and thus receive impressions that otherwise could not be detected. In this connection, he spoke of the delicate gearing required for keeping the telescopes on the stars automatically and said that in the most carefully cut gears errors as great as one sixteenth of an inch appeared. This had to be eliminated by careful grinding.

He then showed views of his own shops, where much work in the construction of astronomical instruments has been done and is being done. Among these was that of a six-foot diameter mirror that was in the course of preparation. He told of the great accuracy and delicacy with which the various gratings, mirrors, and prisms had to be handled, laying great stress upon the effect of variations in temperature in the vicinity of these bodies. It is possible to measure to one millionth of an inch and to detect errors to one five millionth

of an inch. He said that we must remember any machine that does the work for which it was designed is accurate enough.

Dr. Brashear explained why the mirrors used in astronomical work were of such great thickness, saying that the least flexure was obtained when the thickness was one sixth of the diameter. These large and valuable objects are shipped in loose packing in a box and this box is then packed in another box. This method has proved entirely satisfactory. He also described a simple method used in obtaining a plane surface. This is done by matching three surfaces, and using sodium light as a detector. Prof. W. Trinks, Mr. Estep and Mr. Williams took part in the discussion which followed.

CORNELL UNIVERSITY

The Cornell University Student Branch held a public meeting on March 10, at which Prof. H. S. Jacoby of the College of Civil Engineering addressed the members and their friends on the Maximum Spans for Different Types of Bridges. Supplementing his descriptions with lantern slides, he discussed the principal types of such structures from the simple plate-girder to the new Manhattan suspension bridge.

COLORADO AGRICULTURAL COLLEGE

At a meeting of the Colorado Agricultural College Student Branch on March 10, H. A. England gave a detailed and instructive talk on Mining Machinery. This included drills, drilling machinery, and methods of drilling holes and removing material. He spoke also of air compressors and pumps as used in mining.

Mr. Edmonson then gave an account of his visit to the plant of the Commonwealth Edison Company in Chicago. He discussed the coal and water supplies and the railroad facilities, and emphasized the immense size of the boiler plants.

LELAND STANFORD UNIVERSITY

At the regular meeting of the Stanford Branch of the American Society of Mechanical Engineers on March 23 C. J. Cokerly gave a highly interesting and instructive talk on the history of Colored Photography and on his experiences in that line of work. He illustrated his talk with samples of his work.

J. A. Shepard spoke on his experience in hydro-electric work in Colorado, and the difficulties to be overcome in power plant operation.

MASSACHUSETTS INSTITUTE OF TECHNOLOGY

At a meeting of the Mechanical Engineering Society of the Massachusetts Institute of Technology on March 24, F. L. Fairbanks of the Quincy Market Cold Storage Company gave an illustrated lecture on The Design and Construction of a 1000-ton Ammonia Compressor. The possibility of making a larger machine of this nature without any assembly or even assembly drawing was discussed at length by Mr. Fairbanks, for it was in this way that he designed and erected the 1000-ton machine, which is the largest of its kind in the world.

OHIO STATE UNIVERSITY

At a meeting of the Ohio State University Branch on March 19, the following officers were elected for the ensuing year: H. Burnham, chairman; W. M. Leonard, vice-chairman; S. J. Cobb, secretary; M. A. Nettleton, treasurer; A. F. Landefeld, sergeant-at-arms. P. W. Sheatsley, secretary of the branch, gave a short talk on The Generating Plants of the Commonwealth Edison Company of Chicago.

PENNSYLVANIA STATE COLLEGE

The Annual Mechanical Banquet, given by the Juniors of the Pennsylvania State College Student Branch to the Seniors, was held on March 18. The toastmaster was V. D. Longo, '16, vice-president of the branch. The following toasts were given: Strength in Union by J. A. Mease, pro-

fessor of machine design; Our College by H. Diemer; New Methods by J. P. Calderwood, professor of mechanical engineering; Good Fellowship by E. D. Walker, dean of the School of Engineering; Locomotion by A. J. Wood, professor of railway mechanical engineering; Association by E. N. Bates, professor of mechanical engineering; State Students by O. F. Bourke, professor of economics; Engineers of 1915 by W. D. Garman, '15, president of the branch; and Engineers of 1916 by G. Jeffery, '16.

PURDUE UNIVERSITY

Charles J. Peck, M. E., '06, gave a very interesting talk on Valves and Other Fittings Used in Modern Piping, before the Purdue Branch of the A.S.M.E. on March 16.

Mr. Peck outlined very clearly the method of finding any required fitting in the catalogue issued by his company in which 16,500 articles for use in piping work are listed. All fittings are marked with the highest pressures they are designed to stand, and it is the duty of every engineer to see that the pressures are not exceeded.

To withstand these pressures many different materials are needed. Sometimes cast steel is used; sometimes malleable iron or cast iron will suffice. In all fittings where brass and nickel are used special grades of these materials must be provided to suit the different conditions. Hydraulic pressures as high as 5,000 lb. per sq. in. and temperatures of superheated steam upward of 750 deg. Fahr. are often met with.

Mr. Peck next explained the fittings in detail. The most widely used piping formerly was wrought iron, but the modern steel piping has largely superseded it. Most piping now is of the flanged type and several examples were shown by the speaker. Section of gate and globe valves were shown; the former is more expensive and is used on water lines and on large steam lines; the latter is cheaper and is much used for smaller lines. The automatic stop valve for boiler work is a great help in power plant work, as it will cut in or out a boiler as the pressure reaches or drops below the line pressure.

The last branch Mr. Peck described was the modern tilting trap and the drainage and direct return types. The former is very simple, and operates to drain a line of condensed steam without the loss of live steam. The direct return type will force the condensed steam back into the boiler and is a much more efficient means than the ordinary duplex pump when pure water is used. The tilting trap can be used on anything from a heating plant to a modern power plant.

A meeting of the branch was held on March 31. The society was addressed by Frank Rasmussen of the Link-Belt Company of Chicago, who gave an illustrated lecture on The Elevating and Conveying of Materials.

Mr. Rasmussen is a graduate of the mechanical department of the State College of Colorado, and received his degree in 1901. His position with the Link-Belt Company has given him the opportunity to design conveyors for many new and difficult installations, and to investigate many other varied types of elevating machinery. He presented a number of lantern slides illustrative of the conditions commonly met with and of the types of conveyors installed.

Chain is the basis of nearly all conveyors. The common kinds are built up of detachable links, that breakages may be replaced. This detachable chain was developed originally for harvesting machinery to give a flexible as well as positive drive, but its worth has been so well proven that thousands of feet are made annually for all sorts of purposes.

Confining his talk to conveyors and elevators, Mr. Rasmussen illustrated many types of chains; Roller chains provided with hooks for ear haulage in mines; flight conveyors, which scrape the material along in a trough to the desired location; the chain driven combination elevator and conveyor bucket, used especially for coal in power plants like that at Purdue; the overlapping platform conveyor for heavy materials at low speeds, like mine "picking," and the continuous bucket type for similar elevation.

Other types of conveyors for special purposes are the rope conveyors often used in bakeries in connection with spiral chutes. In this connection Mr. Rasmussen mentioned that a conveyor is being developed to run through an oven, that the baking may take place while the bread or cake is in motion, and may be a continuous process. The remaining conveyor which is used at all is the flat belt type, this being one of great capacity at all speeds. The last few illustrations outlined thoroughly the process of washing and drying coal in the modern mine.

L. D. Rowell, of the electrical department, gave a very interesting lecture on The Modern Battleship before the Purdue University Student Branch in the Mechanical building on April 13. He gave a detailed outline from the beginning of the iron clad vessel to the present time, comparing the ships of the United States with those of the other world powers.

The average American layman knows little about the United States navy in reference to its present condition or its development. He is oftentimes influenced by the more rabid newspapers into believing that the navy is useless and that the American ship yards know little about the construction of the modern warship.

Prof. Rowell proved conclusively that this statement was false. He started with the time of the Monitor and Merrimac. This battle was without a doubt one of the most unique naval conflicts ever fought, not because of the number of men killed or the decisiveness of the victory, but because it marked a new era in warfare. It marked the end of one type of vessel and the beginning of another.

Captain John Ericson was the hero of the first battle of the Iron Clad. His name has gone down in history as one of America's greatest engineers.

Prof. Rowell compared very minutely the destructiveness and accuracy of the shells fired from the Iron Clad with those of the present day vessel. One broadside fired from a modern warship will do as much damage at six miles as a continuous fire from the Merrimac did in over four hours at point blank range.

The American Navy degenerated after the Civil War. It became the laughing stock of the world. It took twenty years to build some ships. The year of 1884 marked the beginning of the second era. Important steps were taken about this time to perfect the navy. The armored turreted battleship was introduced and the armored cruiser constructed. Among other types of vessels that have since been built are the hospital ship, the collier, the torpedo boat, the submarine, the destroyer and the dreadnought. Prof. Rowell discussed these, explaining in detail the action of the guns of each type, their destructiveness, accuracy and speed.

The speaker stated that although the navy of the United States according to size, was not the strongest nevertheless it surpassed the navy of any other country in every other respect.

STEVENS INSTITUTE OF TECHNOLOGY

On March 9, James Hartness, president of the Jones & Lamson Machine Company, and past president of the Society, gave a lecture on Machine Tool Design before the Stevens Institute of Technology Student Branch.

On March 10, the Stevens Engineering Society conducted a party of students to inspect the plant of the Astoria Gas Light and Power Company, and another party on March 17 to see the process of manufacture of prepared soups at the plant of the Franco-American Soup Company in Jersey City. The last inspection trip of the year was made on March 24 to Jacob Ruppert's Brewery, New York.

UNIVERSITY OF CALIFORNIA

At a meeting of the University of California Student Branch on March 2, Eugene Arnot gave a talk on the Construction and Care of Exide Storage Batteries. Walter Allat spoke on the Construction of the Edison Storage Cell, and described tests which had been performed upon it.

At a meeting of the branch on March 30, John W. Dinsmore read a paper on Gun Powder Used in Big Guns, deal-

ing also with methods of projectile velocity measurement. The paper was discussed by A. C. Moorhead, H. L. McLean and Mr. Kennedy.

UNIVERSITY OF COLORADO

At a meeting of the University of Colorado Student Branch on March 25, the following officers were elected: Edison B. Good, president; Barrett Morrison, vice-president; C. Roy Goodner, secretary-treasurer.

Mr. Bagnall, salesman for the American Radiator Company in Denver, Colo., gave a brief history of Heating and Ventilation from the ancient Egyptians down to the present time. He said that the air valve for steam radiators as well as many others means of heating and appliances for steam radiators were the inventions of Colorado men, for instance the blast heating system. The United States leads in methods of ventilation, although some few ideas have come from England and Germany. The speaker suggested that radiators on account of their unsightliness be placed within base-boards, window-frames or door-frames. Typical problems of heating were given, showing the relation of the heat required to radiators, size of boilers, size and height of chimney and size of pipes. The various types and styles of steel and cast-iron boilers, valves, thermostats and temperature regulators were also discussed.

UNIVERSITY OF ILLINOIS

At a meeting of the student branch of the University of Illinois on February 26, the four-reel film, From Molten Steel to Automobile, issued by the Maxwell Company, was presented. This showed all the details in the construction of a modern gasoline car. Beginning with crude steel, the processes of casting and forging were shown in their entirety. After this, came the making of the various other parts such as the chassis and the minor engine parts.

At a meeting on March 12, H. T. Seovill of the accountancy department of the same company gave an address on Opportunities for Mechanical Engineers in Cost Accounting. In his opinion cost accounting and efficiency engineering offer a broad field for the technically trained engineer who is keenly observant and possesses the ability to handle men. The efficiency engineer reduces the cost of production by half. At the Ford factories men working at benches were spending four of their nine hours a day in walking, and the efficiency engineer was the man who saved steps. The man who can save time and money in production will benefit consumer and producer alike.

UNIVERSITY OF KENTUCKY

A special meeting of the University of Kentucky Student Branch was held on February 24, at which Calvin W. Rice, Secretary of the Society, gave a very interesting talk. He spoke first about the plans of the Society in forwarding the work among the student branches. The latter part of his talk was devoted to an account of the trip to Germany in 1913, and was illustrated with lantern slides. Among the most interesting views were those showing the German Museum in Munich which contains a working model of possibly every piece of machinery ever made. Each model is constructed so that the actual operation of the machine may be seen. An extraordinary feature of this museum is that no money has been donated by the government toward the collection of these models.

UNIVERSITY OF MAINE

At the last meeting of the University of Maine Student Branch, G. G. Holbrook of the Bath Iron Works delivered a very interesting and instructive lecture on Cost Estimates of Engineering. He divided his subject into the following topics: material, labor, overhead, margin, profit and delivery. The various methods of working out the cost of these several items were discussed by the speaker.

UNIVERSITY OF MICHIGAN

The University of Michigan Student Branch held a regular meeting on April 2 at which Prof. John R. Allen, dean of

the Robert Engineering College of Constantinople, gave a very interesting lecture on Engineering in Turkey. The speaker first discussed the character and traits of the Turkish people, and then discussed the City of Constantinople, illustrating his talk with lantern slides. He told of the commercial facilities of the famous old city due to its excellent location. Constantinople has sixty-five miles of water front; the fronting on the Bosphorus being especially valuable as the Bosphorus is deep right close to the shores.

UNIVERSITY OF MINNESOTA

On March 3, an open lecture under the auspices of the Minnesota Student Branch was given by a representative of the Carborundum Company to the whole Engineering College. The lecture was illustrated with lantern slides, and showed in great detail the manufacture of the carborundum itself and that of the various types and sizes of grinding wheels used.

On March 11, the branch held a meeting at which Prof. W. T. Ryan, of the department of electrical engineering, spoke on Diversity Factors in Central Station Operation. The diversity factor shows the ratio between the power actually used by a consumer and that which the apparatus installed for him can give if called upon. The factor has been investigated for a number of cities, and Professor Ryan has carried out such an investigation for the principal cities and towns of Minnesota. The lecture was exceedingly interesting and practical.

On March 18, under the auspices of the branch a reel of Ford films was shown to the Engineering College. Prof. S. C. Shipley of the mechanical engineering department, who visited the plant last summer, gave an explanation of the film. The lecture showed the famous assembling conveyor which makes the "1000 cars a day" possible. It also showed the complete assembling of a car from the point where the frame is placed on the conveyor to that where the car runs out of the shop under its own power. The audience filled the Engineering Auditorium to capacity.

UNIVERSITY OF MISSOURI

At a meeting of the University of Missouri Student Branch on March 25, W. A. Sloss gave a talk on The Oil Industry. He described the methods employed in prospecting for oil, opening new wells and installing machinery, and explained the work in detail up to the delivery of the crude oil at the refinery.

WORCESTER POLYTECHNIC INSTITUTE

By invitation of the Alumni and the local members of The American Society of Mechanical Engineers, the Worcester Polytechnic Student Branch were present on April 8, at the organization of the Worcester Section, Am. Soc. M. E. Ex-Mayor James Logan, Manager of the United States Envelope Company, presided. He spoke briefly of the need of an organization to bring together the varied engineering interests of the locality; and then called upon Dr. Ira X. Hollis, President of the Worcester Polytechnic Institute, who called attention to the help which this section could give to the engineering college of which he is the head and especially to the Student Branch.

Calvin W. Rice, Secretary of the Society, was introduced and spoke of the value of the various local sections of the Society, placing particular emphasis upon the growing interests of the professional engineer in civic affairs.

An interesting address on the Submarine was given by R. H. M. Robinson, formerly Naval Constructor, and now general manager of the Lake Torpedo Boat Company. The speaker began with a historical sketch of the submarine, the first successful one being that of David Bushnell, in 1773, followed by Robert Fulton's submarines. He then gave a brief description of the various submarines being built in the United States, Germany, France and Italy, and supplemented his description with lantern slides showing the five types of submarines. These are the Holland and the Lake, which are built in the United States; the Lebel, the French boat; the Krupp-Deceville, Germany's type of boat; and

the Fiat-Laureti, which is of Italian design. There is practically no protection for a battleship against a submarine. The battleship of the newest type represents an expenditure of about \$16,000,000 and this great fighting machine can be put out of commission, if not sunk, by a single torpedo from a submarine. The United States is building submarines which will have a cruising radius of from 1000 to 5000 miles. The German submarines have been working in a radius of from 1100 to 1200 miles and this is considered remarkable. While it is not probable that the present submarine is all that is necessary in naval warfare, it is a beginning of a new style of naval armament. For motive power, submarines depend upon storage batteries and combustion engines, but it is likely that steam driven submarines will soon be built. There have been steam submarines, but with poorly developed engines and boilers, they were found impracticable. With the newer developments in steam engines and high pressure boilers, however, the steam type will be a success.

Commodore Robinson said he believed that the German submarines were using a short range torpedo with an extremely heavy charge for operating against war ships, but with an extremely light charge when attacking merchant vessels. He called the Whitehead torpedo the best developed mechanism in the world and told of the exhaustive tests given each torpedo before sending it out to be used.

EMPLOYMENT BULLETIN
